2008 first beam

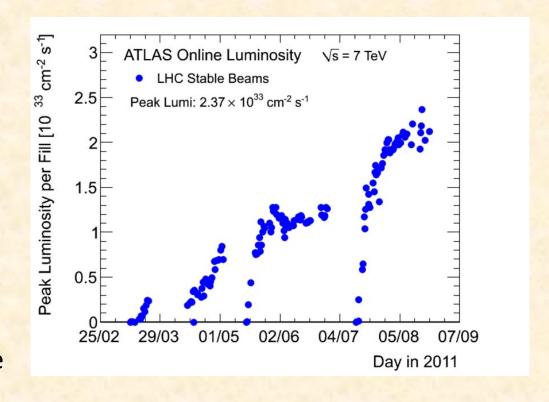

2010 first collisions at 3.5 TeV beam energy

2015 collisions at ~design energy (plan)

we are already late if we want to get a new machine by ~2040! >30 years!

A complex enterprise

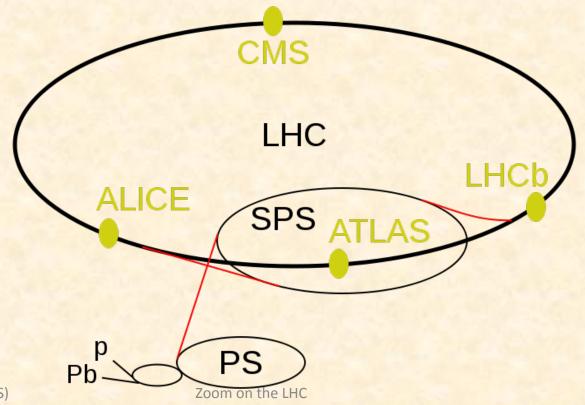

- Beyond the particle physics challenges associated with the construction of the detectors and the analysis of the data, building and operating the LHC machine was also an immense challenge involving a large number of skills.
- The machine has not yet reached its full potential and the engineers running it improve its performance all the time.

References: http://lhc.web.cern.ch/lhc/LHC-DesignReport.html and « The LHC Machine, Lyndon Evans and Philip Bryant 2008 JINST 3 S08001 doi:10.1088/1748-0221/3/08/S08001 »

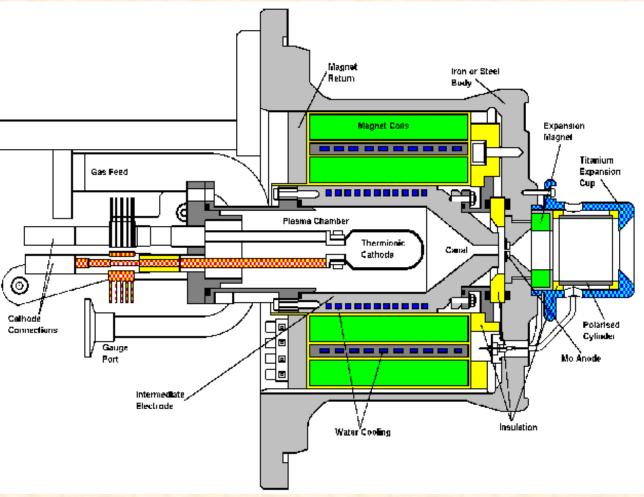

The injection chain

- Particles can not directly be produced and accelerated in the LHC, several preliminary steps are necessary.
- Let's follow a proton from the source to the collisions...

Proton source

 Particles are extracted by ionisation of hydrogen as in a device called "Duoplasmotron Proton Ion source"

Linac

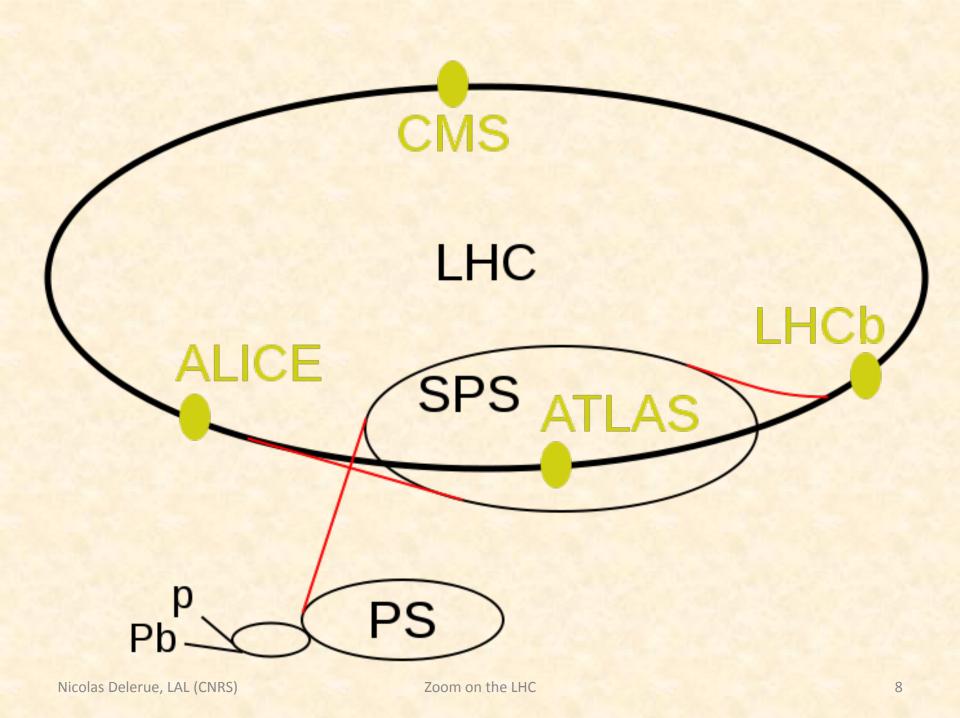

Source | Company | Compan

- After the source the protons are accelerated in a linac.
- As the protons gain speed they travel longer distance in a RF cycle and therefore the length of the tubes must be increased.
- At the end of the Linac the protons reach an energy of 50 MeV.

AccSys Technology, Inc.

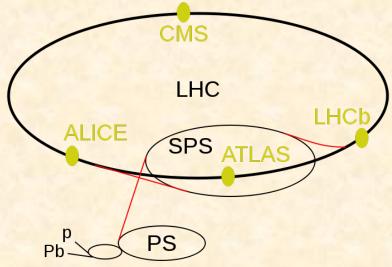

Pre-acceleration rings

 At 50 MeV the energy of the protons is too low to be injected in the LHC.

 Several intermediate rings are necessary to bring their energy to the LHC injection energy.

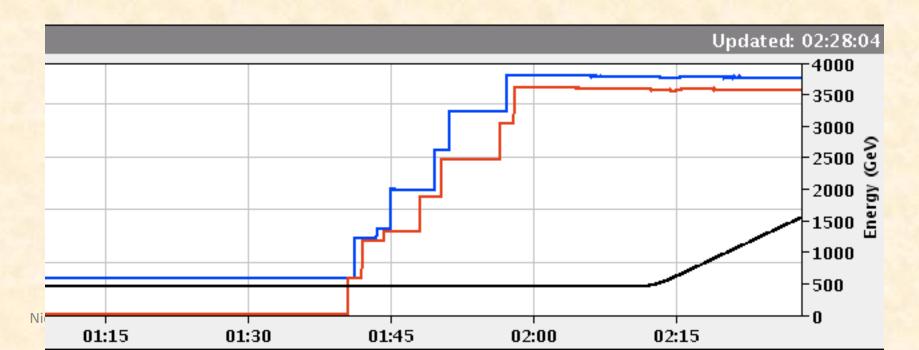

- To save space the first of these rings, the PS booster is made of 4 rings stacked on to each other!
- All these rings use pulsed magnets which allow to change the beam configuration very quickly.
- The PS was built in 1959, the PSB in 1972 and the SPS in 1976.

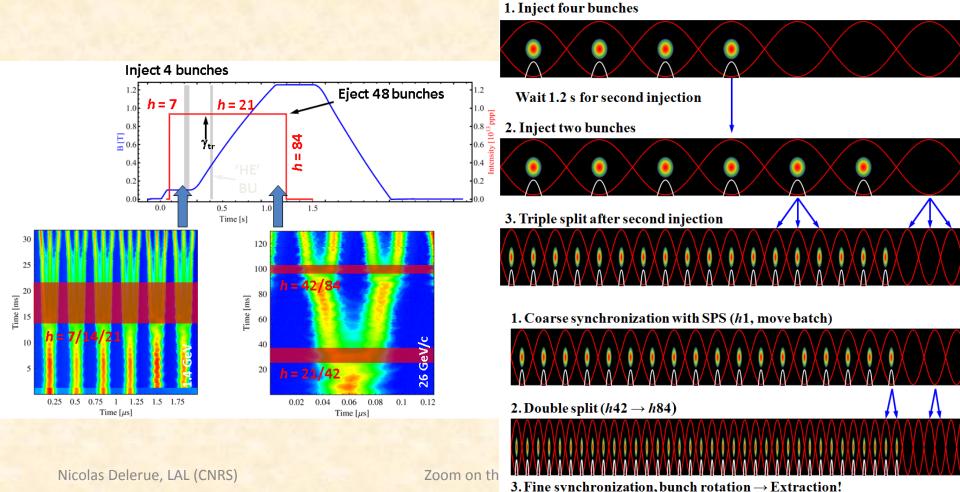

Why pre-acceleration rings?

- In a synchrotron the strength of the magnets must be increased when the energy of the particles is increased.
- It is cheaper to have magnets (and power supplies) with a limited dynamic range.
- As the energy of the beam increases its emittance (and therefore its size) decreases.
 - Early accelerators in the acceleration chain must have a wide aperture whereas the LHC has a small aperture (a bunch from the Linac would not fit in the LHC).

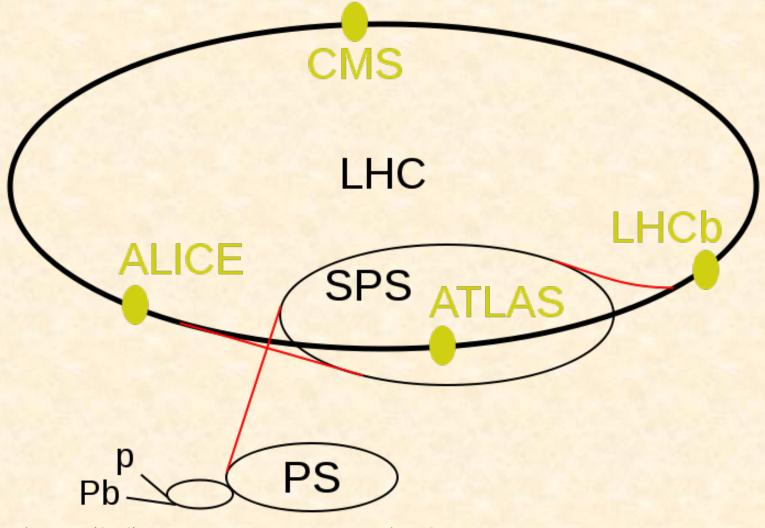

Protons bunch splitting

- Another purpose of the PS is to adapt the bunch structure from the Linac to the requirements of the LHC.
- The RF of the PS is used to split 8 proton bunches into 84 bunches!

Multi turn extraction from the SPS

The LHC itself

Quizz

 Suggest reasons to explain the limitations of the parameters in the table.

	2010	2011	2012	Nominal
bunch spacing [ns]	150	50	50	25
no. of bunches	368	1380	1380	2808
beta* [m] ATLAS and CMS	3.5	1.0	0.6	0.55
max. bunch intensity [protons/bunch]	1.2 x 10 ¹¹	1.45 x 10 ¹¹	1.7 x 10 ¹¹	1.15 x 10 ¹¹
normalized emittance [mm-mrad]	~2.0	~2.4	~2.5	3.75
peak luminosity [cm ⁻² s ⁻¹]	2.1 x 10 ³²	3.7 x 10 ³³	7.7 x 10 ³³	1.0 x 10 ³⁴

Answer

- Bunch spacing: if the bunches are too close they affect each other with their wake.
- Beta: if the bunches are too small, internal effects (space charge, IBS,...) can destroy the bunches...
- Intensity: It is difficult to accumulate charge in a bunch. Losses all along the injection chain must be well controlled.

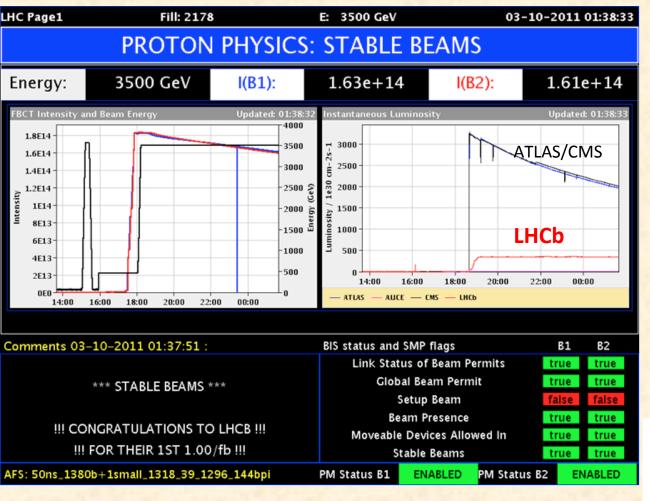

Z → μμ event from 2012 data with 25 reconstructed vertices

pile up

operation
in 2015

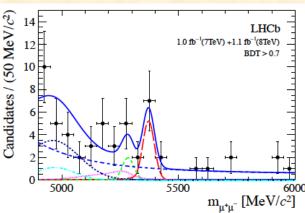

LHCb

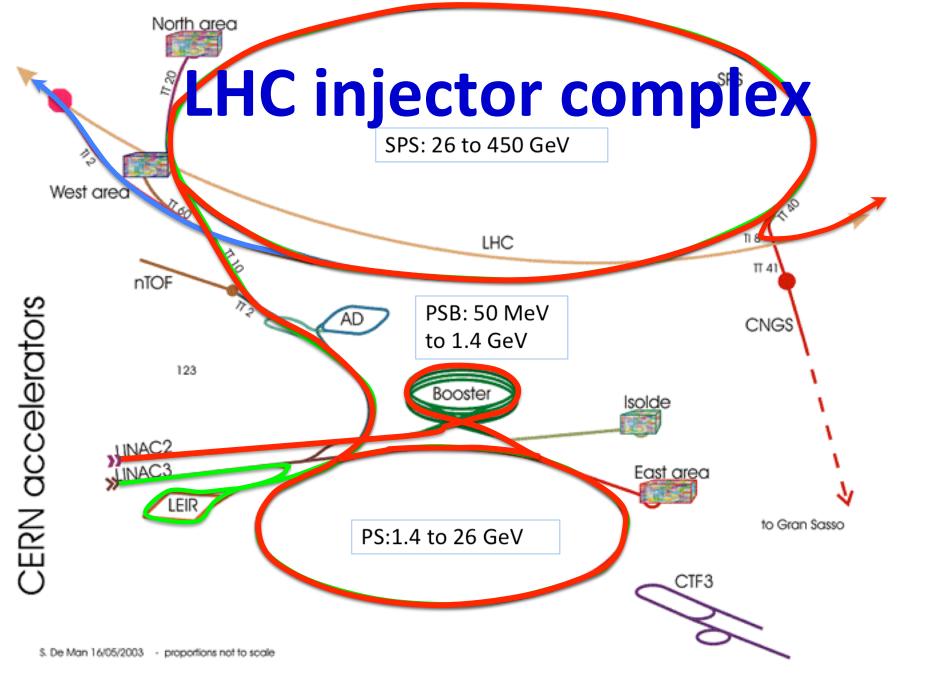

luminosity levelling at around 4e32 cm⁻²s⁻¹ via transverse separation (with a tilted crossing angle)

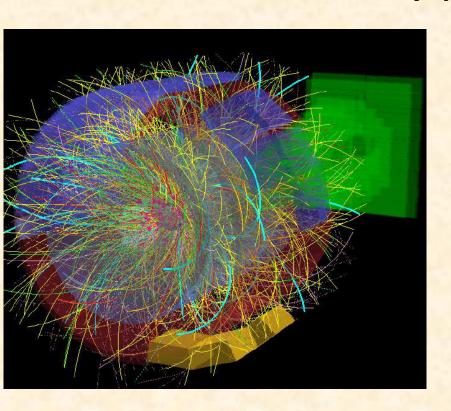

not completely trivial!

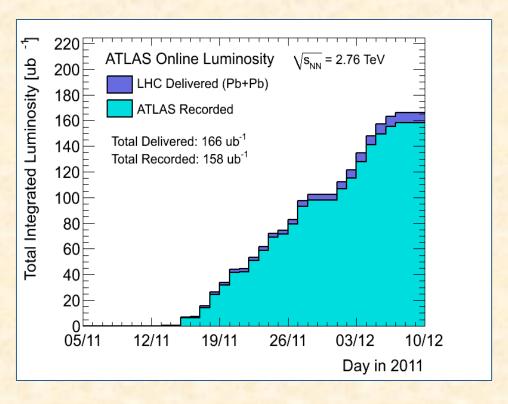

first evidence for the decay $B_s -> \mu^+ \mu^-$

Pb-Pb

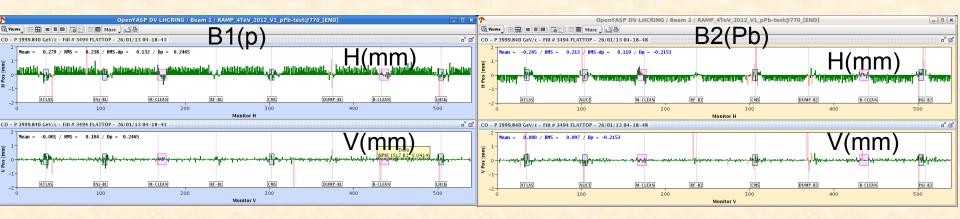

- good performance from the injectors bunch intensity and emittance
- preparation, Lorentz' law: impressively quick switch from protons to ions
- peak luminosity around 5 x 10^{26} cm⁻²s⁻¹ at 3.5Z TeV (2011) nearly twice design when scaled to 6.5Z TeV

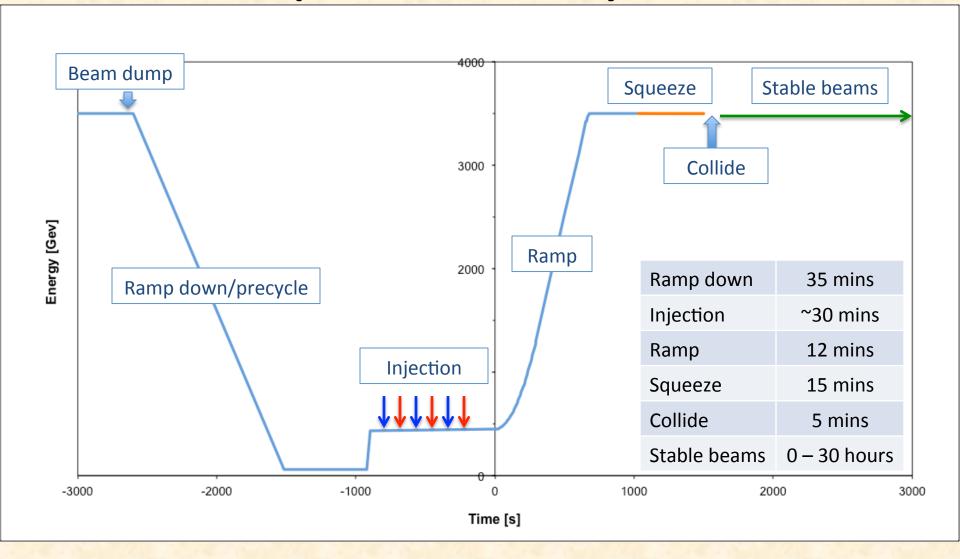

proton-lead

- beautiful result in early 2013
- final integrated luminosity above experiments' request of 30 nb⁻¹
- injectors: average number of ions per bunch was ~1.4x10⁸ at start of stable beams, i.e. around twice the nominal intensity

beam orbits at top energy with RF frequencies locked to Beam 1

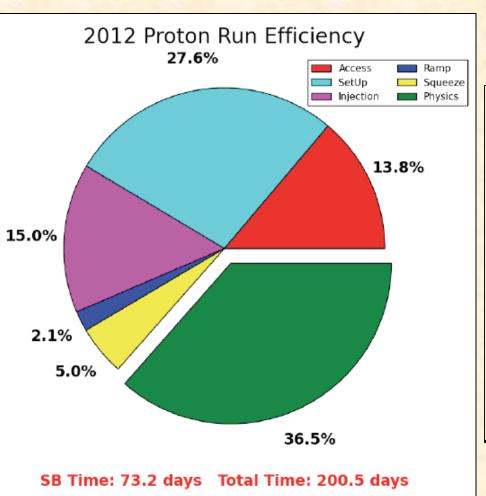

operational cycle

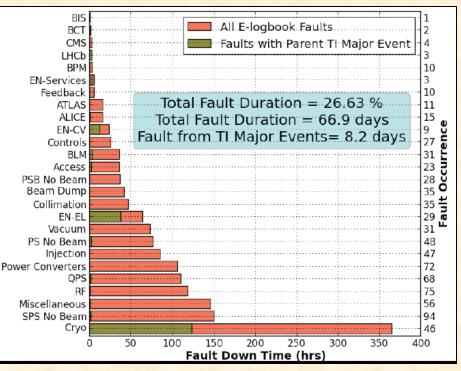

turn around 2 to 3 hours on a good day

availability

- "There are a lot of things that can go wrong it's always a battle"
- Pretty good availability considering the complexity and principles of operation

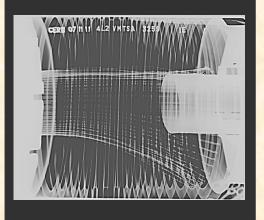

Cryogenics availability in 2012: 93.7%

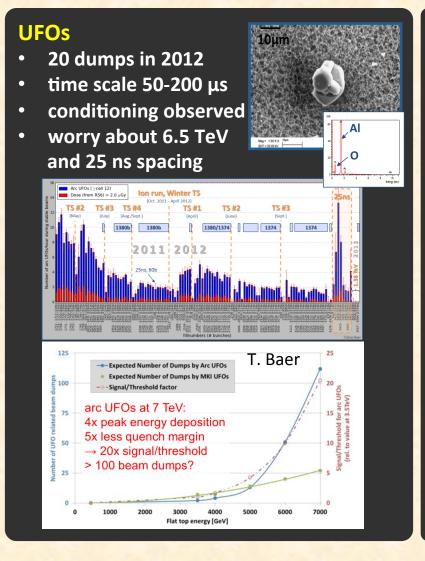

M. Lamont, IPAC'13

some issues in 2011-12 operation

Beam induced heating

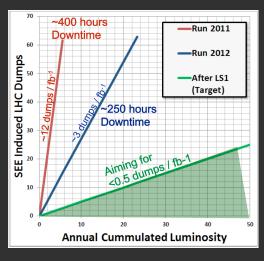

- Local non-conformities (design, installation)
 - injection protection devices
 - sync. Light mirrors
 - vacuum assemblies

Radiation to electronics

- concerted program of mitigation measures (shielding, relocation...)
- premature dump rate down from 12/ fb⁻¹ in 2011 to 3/ fb⁻¹ in 2012

"All Clear" for LHC UFOs?

UK closed UFO desk after 50yrs and no 'potential threat'

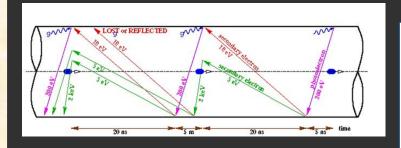

Jun 21, 2013

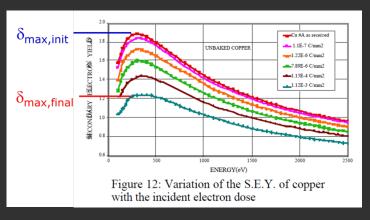

The British government finally shut down a special unit investigating UFO sightings after more than 50 years as it was a drain on resources and not a single report ever revealed " a potential threat to the United Kingdom," newly released government files showed Friday.

another issue in 2011-12 operation

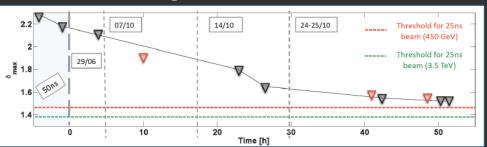

Electron cloud

- beam induced multipactoring process, depending on secondary emission yield
- LHC strategy based on surface conditioning (scrubbing runs)
- worry about 25 ns (more conditioning needed) and 6.5 TeV (photoelectrons)

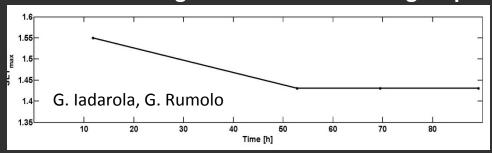

25-ns scrubbing in 2011 – decrease of SEY

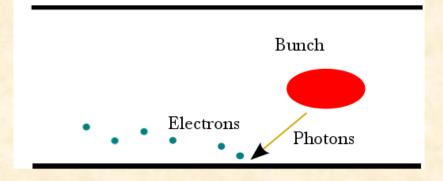

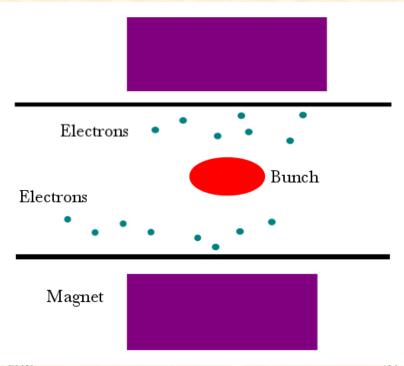

25-ns scrubbing in 2012 – conditioning stop?

Electron cloud effect

- Radiation from a bunch can extract electrons (and ions) from the beam pipe and from residual gas in the vacuum.
- These electrons fall back and get re-absorbed with a certain time constant.
- However if the bunch frequency is too high these electrons (and ions) will accumulate in the beam pipe and shield the beam from the magnetic elements.
- Special coatings, beam pipe geometries and bunch repetition patterns can mitigate this problem to some extent.
- This is one of the main limitations to increasing the

Long Shutdown 1 - motivation

after 2008 incident partial consolidation & related problem of imperfect *Cu* stabilizer continuity discovered

in 2010-12 LHC operated at 7 & 8 TeV c.m. beam energy to avoid any risk

presently: Long Shutdown 1 (LS1) ~2 yr to prepare LHC for 13-14 TeV c.m., detector upgrades in parallel

2008 "incident"

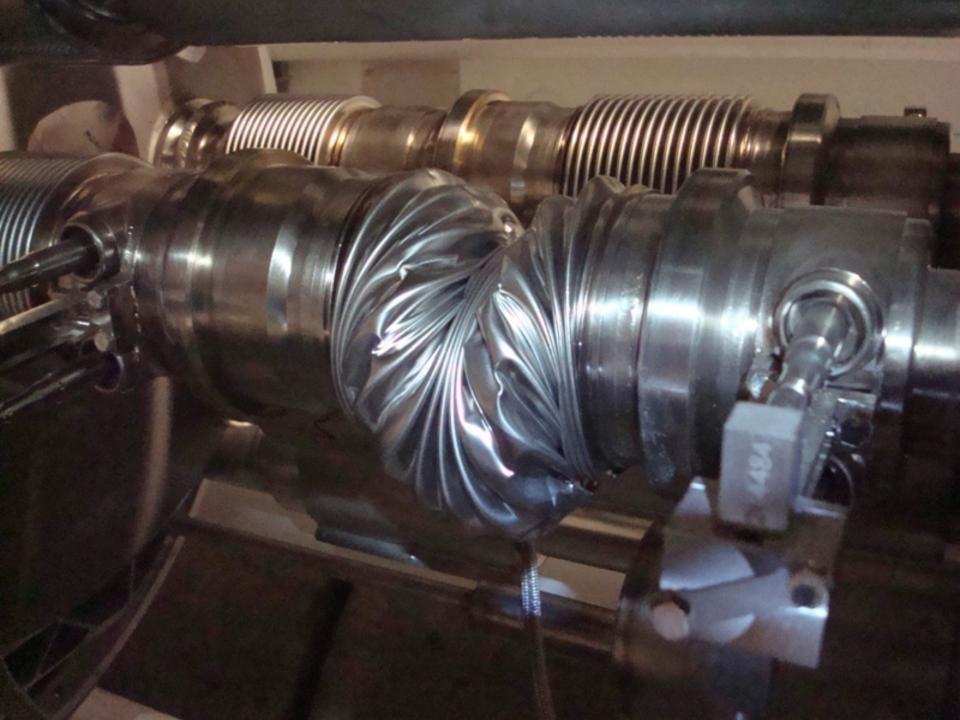

A faulty bus-bar (SC splice) in a magnet interconnect failed, leading to an electric arc which dissipated some 275 MJ

This burnt through beam vacuum and cryogenic lines, rapidly releasing ~2 tons of liquid helium into the vacuum enclosure

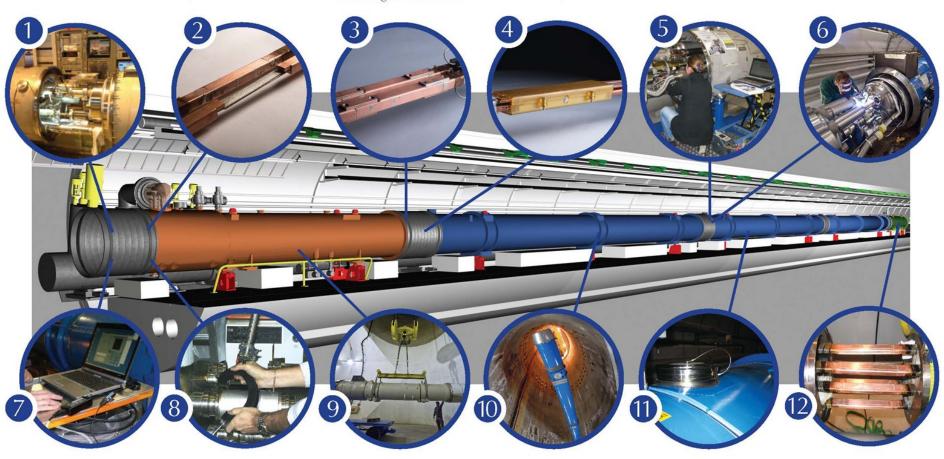

The main 2013-14 LHC consolidations

1695 Openings and final reclosures of the interconnections

Complete reconstruction of 1500 of these splices

Consolidation of the 10170 13kA splices, installing 27 000 shunts Installation of 5000 consolidated electrical insulation systems 300 000 electrical resistance measurements

10170 orbital welding of stainless steel lines

18 000 electrical Quality Assurance tests

10170 leak tightness tests

4 quadrupole magnets to be replaced

15 dipole magnets to be replaced

Installation of 612 pressure relief devices to bring the total to 1344

Consolidation of the 13 kA circuits in the 16 main electrical feedboxes

2015 - post LS1

- energy: 6.5 TeV (magnet retraining)
- bunch spacing: 25 ns
 - pile-up considerations
- injectors potentially able to offer nominal intensity with even lower emittance

	Number of bunches	lb LHC FT[1e11]	Emit LHC [um]	Peak Lumi [cm- ² s ⁻¹]	~Pile-up	Int. Lumi per year [fb ⁻¹]	
25 ns low emit	2520	1.15	1.9	1.7e34	52	~45	

expected maximum luminosity from inner triplet heat load (collisions debris) 1.7×10 ³⁴ cm⁻²s⁻¹±20%

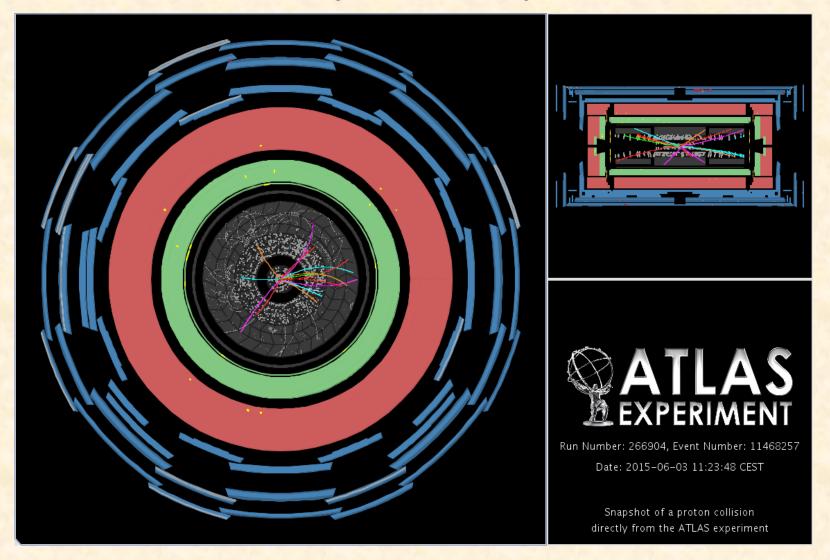

uncertainties for 2015:

- electron cloud
- UFOs

both get more difficult at 25 ns & at higher energy

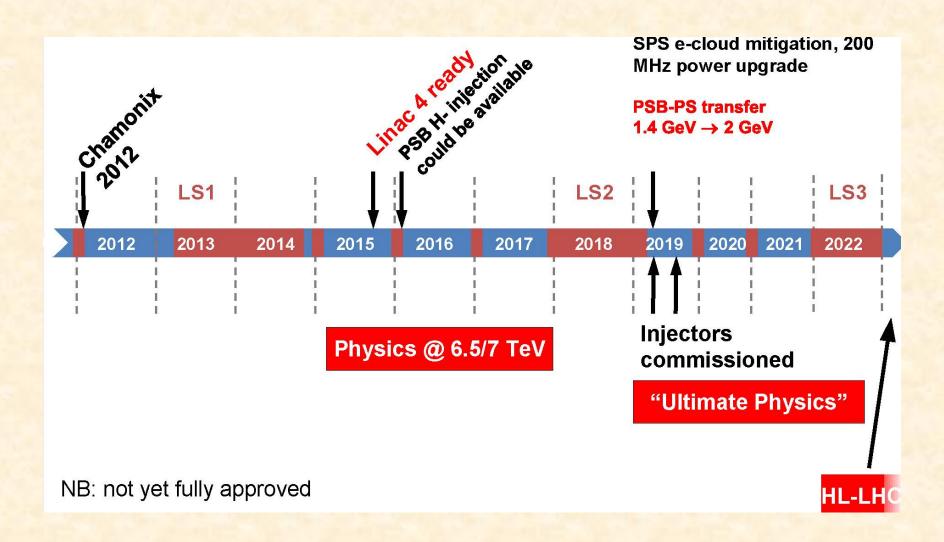

energy (limited by retraining)

And yesterday...

The first physics events of run 2 were recorded!

example LHC time line - next ten years

Linac4 (160 MeV H instead of 50-MeV p)

352.2 MHz

Linac4 could double the beam brightness injected into the booster, but there may be other bottlenecks downstream (e.g. PS injection)

LHC luminosity forecast

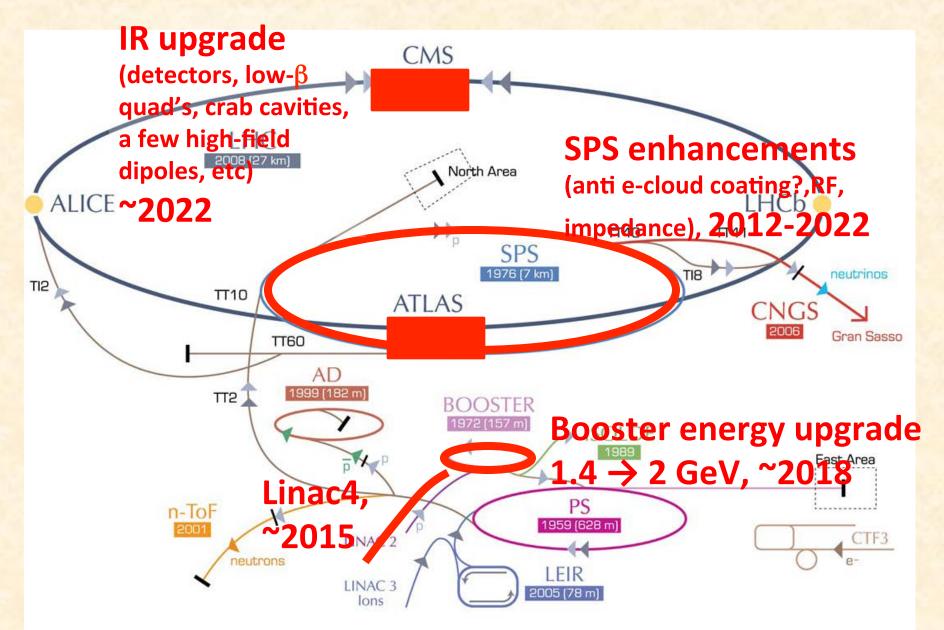

~30/fb at 3.5 & 4 TeV **2012 DONE**

~400/fb at 6.5-7 TeV **2021** goal (?)

~3000/fb at 7 TeV 2035 goal (??)

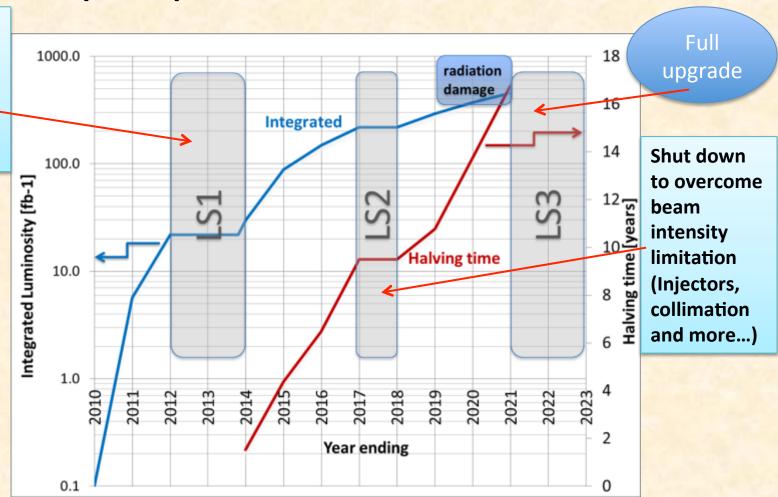

to obtain 3000/fb by 2035 we need the **HL-LHC**

HL-LHC — modifications

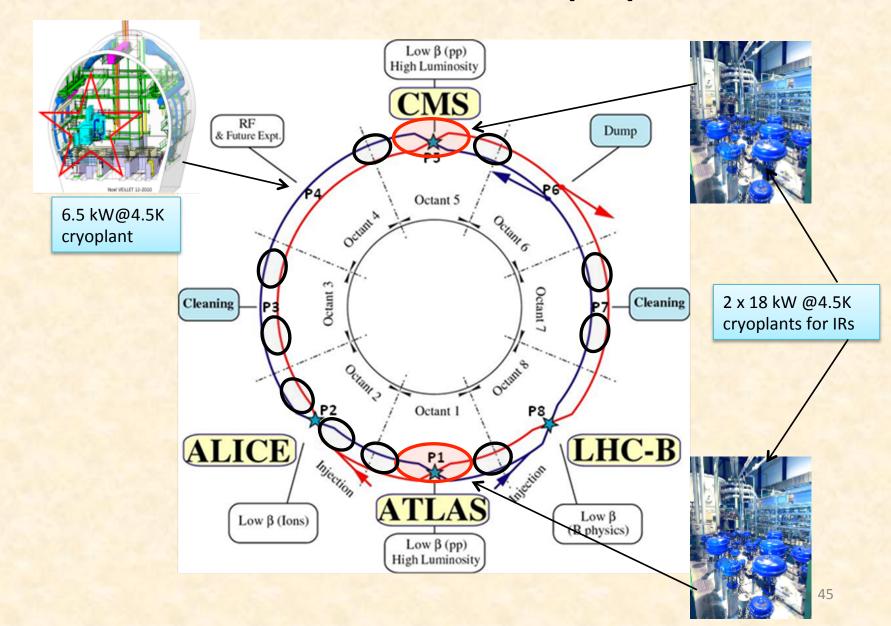

(HL-)LHC Time Line

Shut down for interconnects to overcome energy limitation (LHC incident of Sept. 2008) and R2E

two reasons for HL-LHC: performance & consolidation

Next: 2-m single bore, then 2-in-1

SC link

- move radiation sensitive power converters away
- from machine
- first prototype, 20 m
 20 kA, under test at

 also of interest for electrical power distribution tests of novel MgB₂ and HTS (YBCO and BSCCO) cables

HL-LHC optics

S. Fartoukh

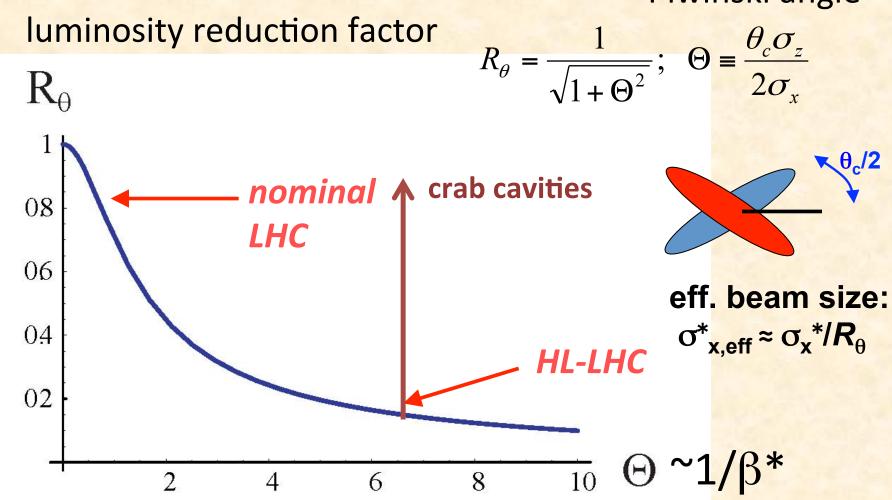

Achromatic Telescopic Squeeze (ATS), «fully proven» MDs ($\beta^* = 15$ cm «easy», room for $\beta^* \sim 10$ -12 cm)

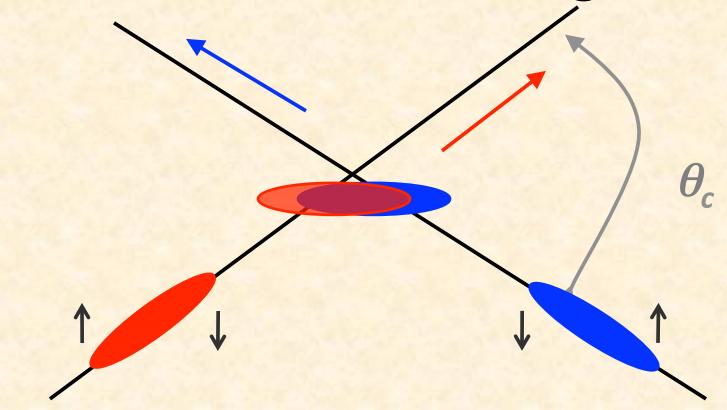

typical ATS collision optics with IR1 & IR5 squeezed down to β^* =10

luminosity reduction due to crossing angle is more pronounced at smaller β^*

"Piwinski angle"

schematic of crab crossing

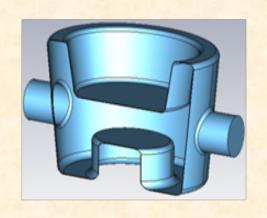

- RF crab cavity deflects head and tail in opposite direction so that collision is effectively "head on" for luminosity and tune shift
- bunch centroids still cross at an angle (easy separation)
- 1st proposed in 1988, used in operation at KEKB since 2007

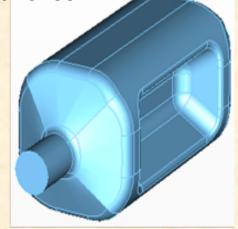

until recently plan was to vary crab cavity voltage for leveling, but this would change size of luminous region & is disliked by experiments (instead leveling by β^* or offset?)

HL-LHC needs compact crab cavities

only 19 cm beam separation, but long bunches

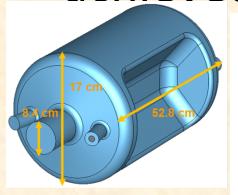

Final down-selected compact cavity designs for the LHC upgrade: 4-rod cavity design by Cockcroft I. & JLAB (left), $\lambda/4$ TEM cavity by BNL (centre), and double-ridge $\lambda/2$ TEM cavity by SLAC & ODU (right).

Prototype compact *Nb-Ti* crab cavities for the LHC: 4-rod cavity (left) and double-ridge cavity (right).

breaking news – PoP double-ridge cavity achieved 7 MV deflecting voltage cw

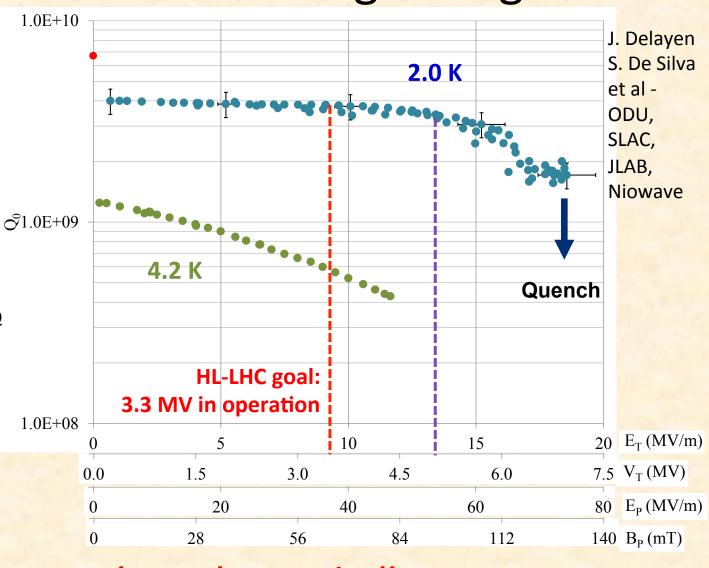

Expected

$$Q_0 = 6.7 \times 10^9$$

- At R_S = 22 n Ω
- And R_{res} = 20 nΩ
- Achieved

$$Q_0 = 4.0 \times 10^9$$

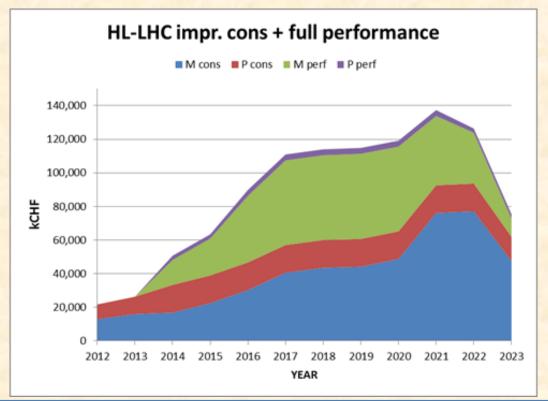

- Achieved fields
 - $E_T = 18.6 \text{ MV/m}$
 - $V_T = 7.0 MV$
 - $E_{P} = 75 \text{ MV/m}$
 - $-B_{P} = 131 \text{ mT}$

better than required!

LHC BEAM INSTRUMENTATION

Beam Profile Monitoring using Wire-Scanners

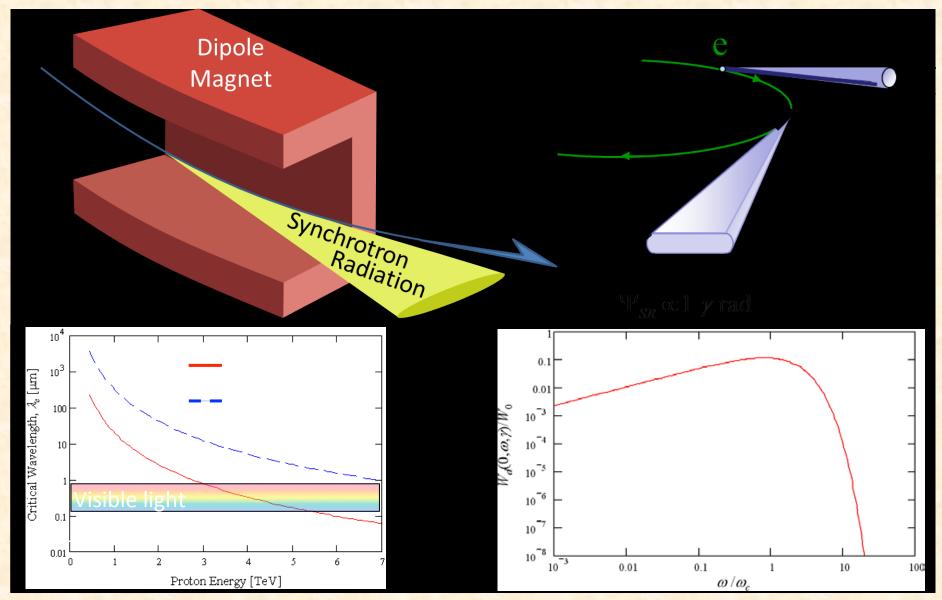

Limitation of WireScanners Wire Breakage – why?

- - Brittle or Plastic failure (error in motor control)
 - Melting/Sublimation (main intensity limit)
 - Due to energy deposition in wire by proton beam
- Temperature evolution depends on
 - Heat capacity, which increases with temperature!
 - Cooling
 - Radiative
 - Conductive
 - Thermionic
 - Sublimation
- Wire Choice
 - 33µm Carbon
 - Good mechanical properties
 - Sublimates at 3915K

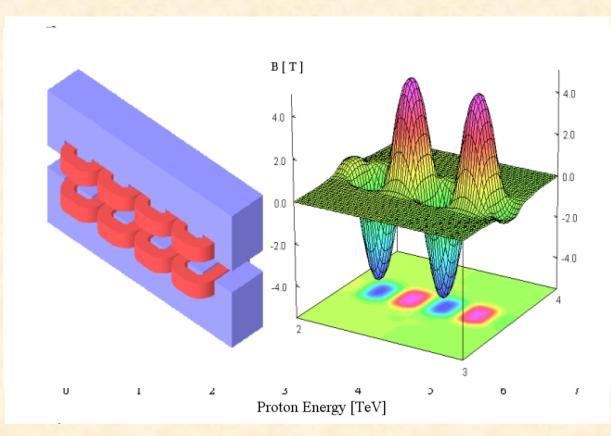

- Typical scan lasts 1 ms & total cooling time constant ~10-15 ms
 - Cooling during measurement negligible

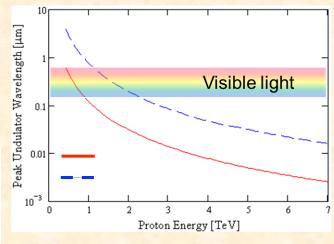

Synchrotron Light in the LHC

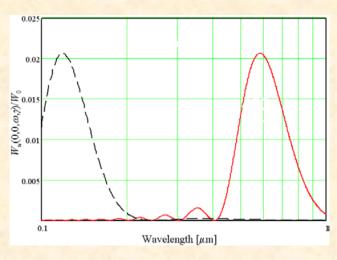

Synchrotron Light in the LHC
At LHC injection energy

- - Visible emission from D3 dipole very low
 - Short superconducting undulator added
 - 2 periods of length 28cm with B field of 5 T

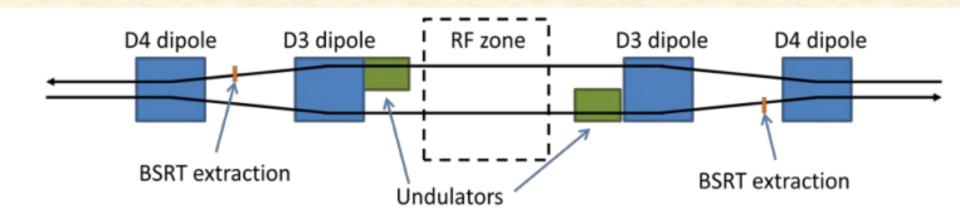

Synchrotron Light in the LHC

- Beam Synchrotron Radiation Telescope
 - BSRT located in Point 4 of the LHC

Synchrotron Light in the LHC

Beam Synchrotron Radiation Telescope

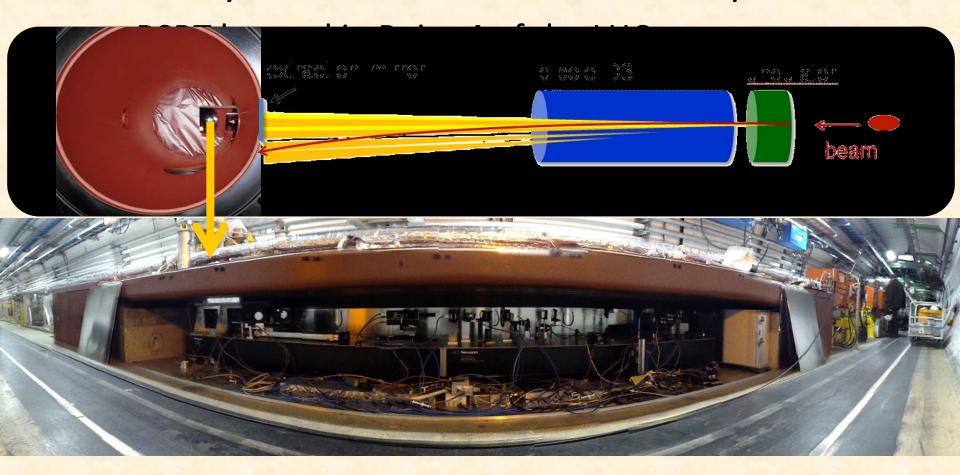

Image Acquisition in the LHC Using a gated intensified camera

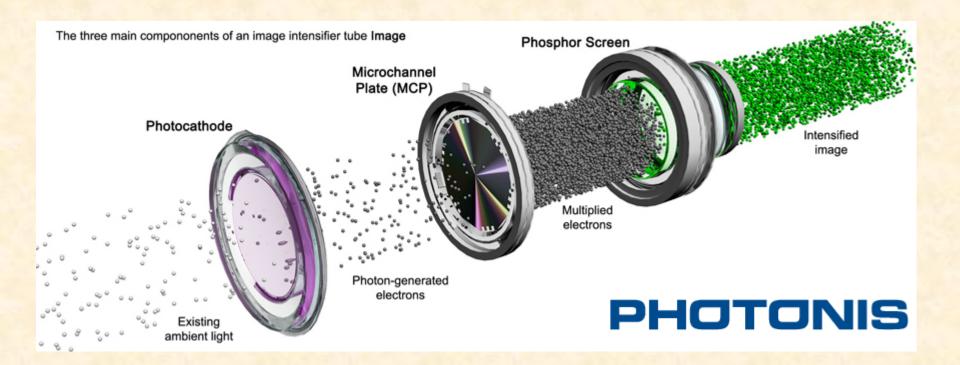

Image Acquisition in the LHC

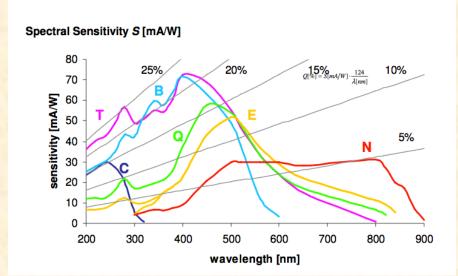

- Proxitronic gated intensified camera
 - Intensifier max trigger rate : 200 Hz (~55 LHC turns)
 - Intensifier min gating: 25ns (1 LHC bucket)
- Present max acquisition rate is 10Hz
 - On paper 10 bunches per second but slower to get statistics

Photocathode response

 cameras equipped with N type during Run I

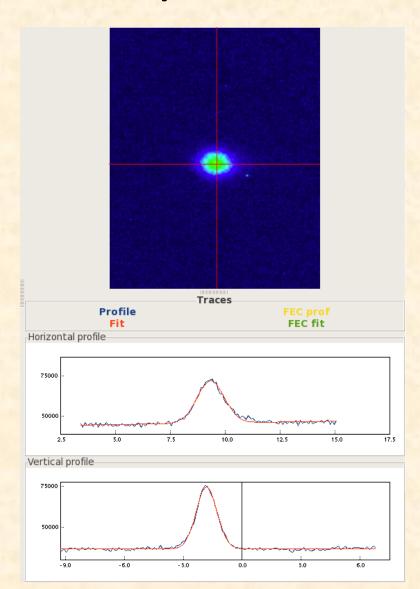

- Will be equipped with T type for Run II
- Overall system sensitivity
 - Enough light to see
 - single proton pilot bunch (5e9p) on a single turn at injection (450GeV)
 - ~20 Ion Pb bunches at injection, averaged over 4 turns

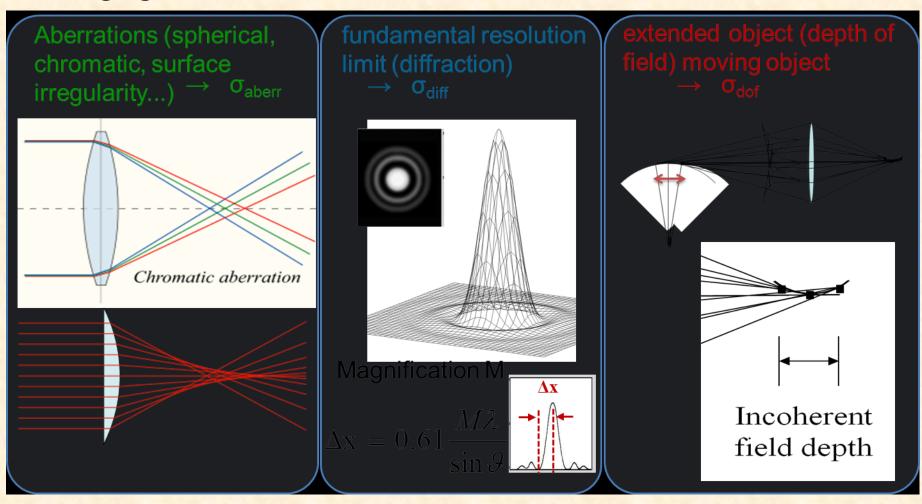

Proton Image Example

- Beam
 - Single bunch ~1.1e11p @3.5 TeV
- Acquistion
 - Accumulated over 4 turns at 200Hz

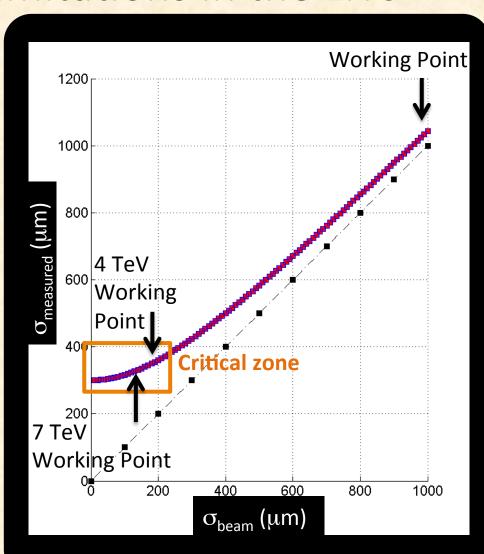

Beam Size Measurement with Synchrotron Light

Imaging Resolution

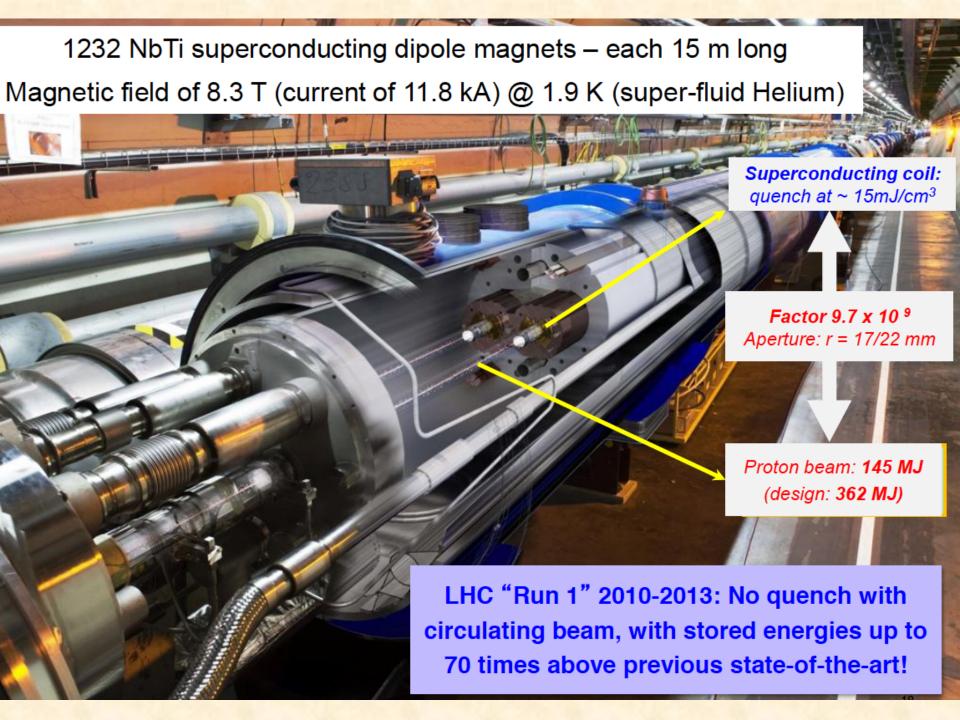

Synchrotron light limitations in the LHC

- σ_{correction}
 - Difficult to model accurately & simulate
 - Therefore experimentally measured ,knowing the real beams size
 - WireScanner cross calibration
- Size measured has to be de-covoluted by a correction factor to obtain the real size
 - For LHC correction factor is of same order as real beam size

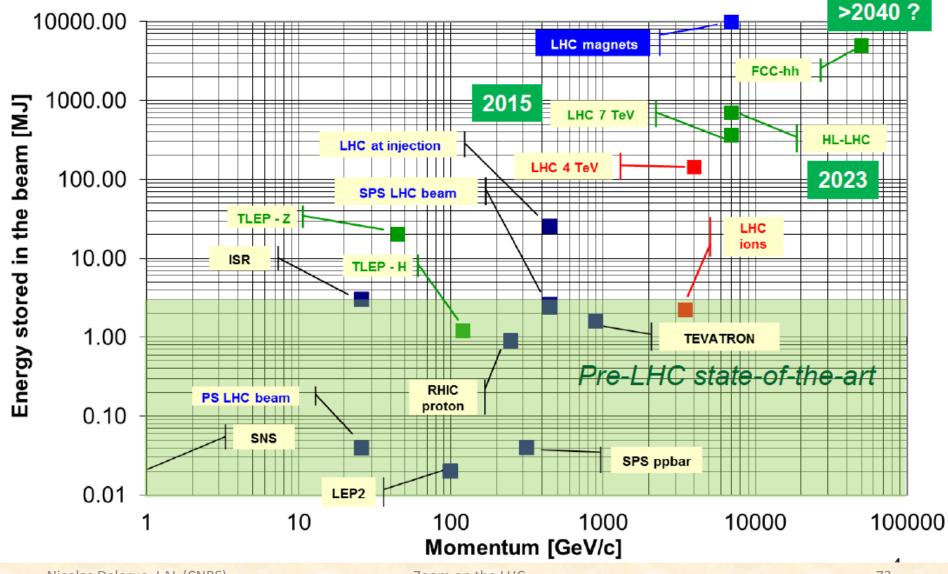

(most slides courtesy of Dr Rhodri Jones and J. Wenninger)

MACHINE PROTECTION AND BEAM LOSS MONITORS

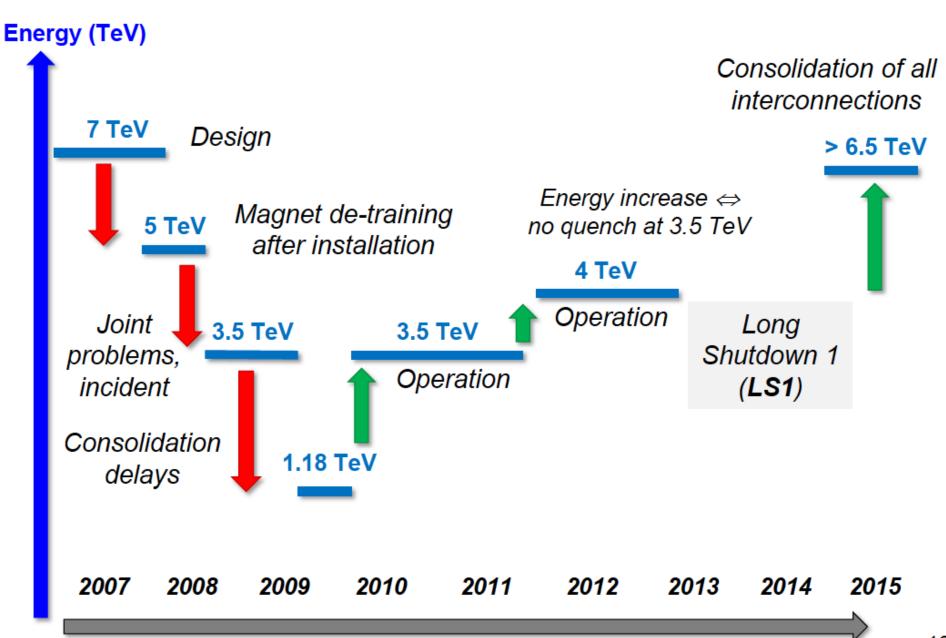

LHC pushes the stored energy from few MJs to > 100 MJs

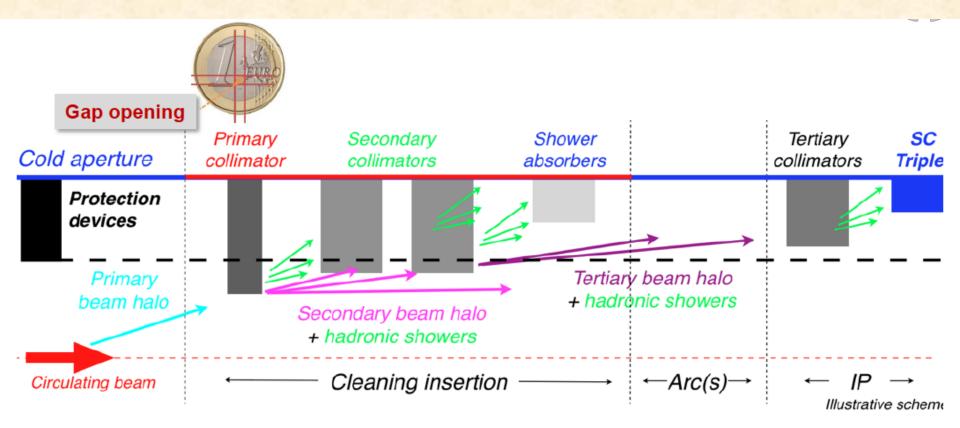

Nicolas Delerue, LAL (CNRS)

Zoom on the LHC

73

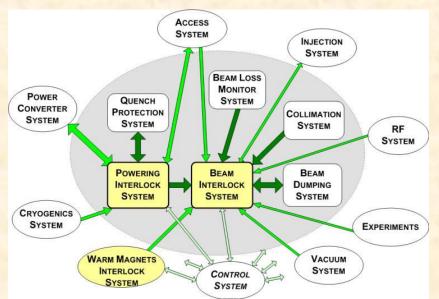

Collimation system

- To be able to absorb the energy of the 7 TeV proton, the LHC requires a multistage collimation system – primary, secondary, tertiary.
- The system worked perfectly so far thanks to excellent beam stabilization and machine reproducibility – only one full collimation setup / year.
 - ~99.99% of the protons that were lost from the beam were intercepted.

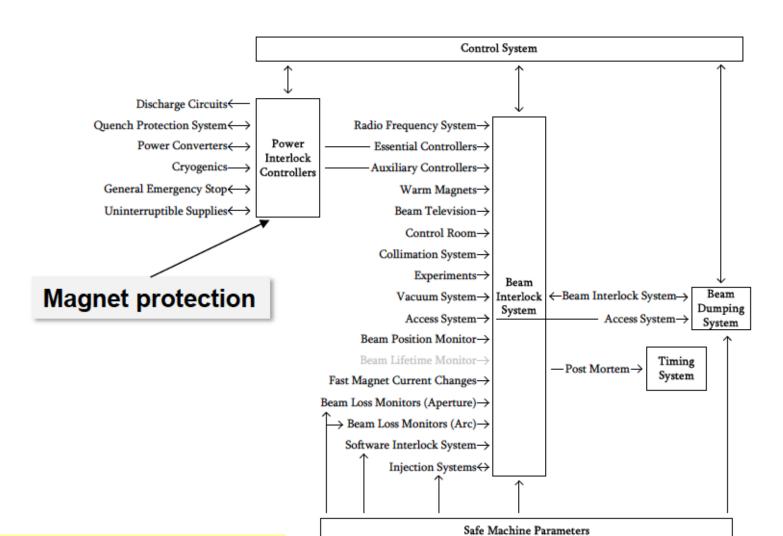

Machine protection system

- The LHC beams carry the same amount of energy than a jumbo plane at take-off!
- If a beam is sent on the beam pipe accidentally it could make serious damages!
- A complex "machine protection system" is used to monitor the machine at all time and prevent injection or dump the beam if a fault is detected.
- A system of flags and permits is used to prevent any situation that might led to significant damages.

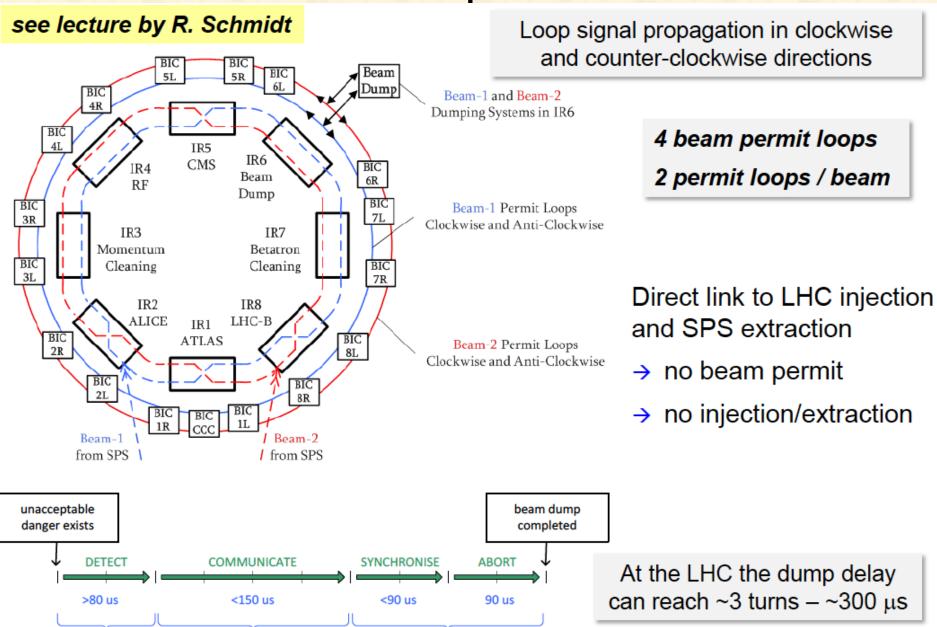

MPS

- The LHC beam interlock system (BIS) has 189 inputs from client systems (including injection).
- Behind each input that can be many individual tests / interlocks.

Beam permit

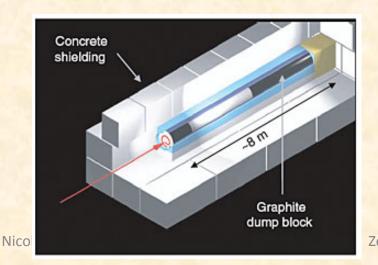

Beam Dump

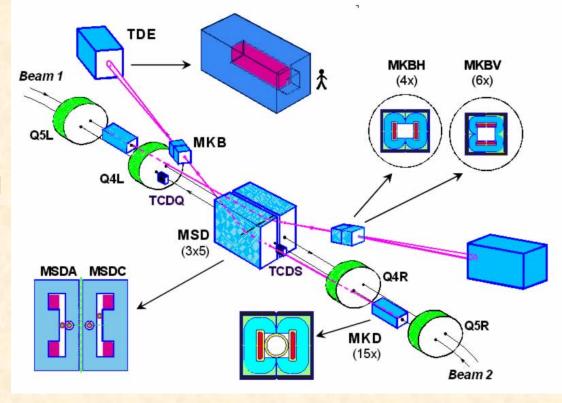

Plant / Sensor

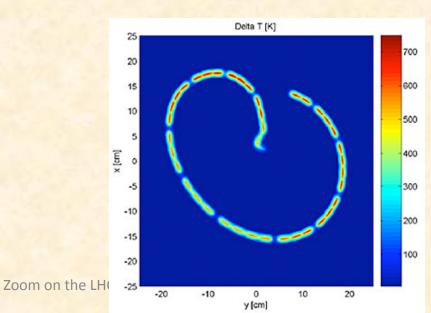

Beam Interlock System

How to get rid of the beams?

- With so much energy stored in the beams they have to be disposed of with care.
- A special area "dumps" has been designated and instrumented for this purpose.
- All the energy can not be disposed of on a single point.

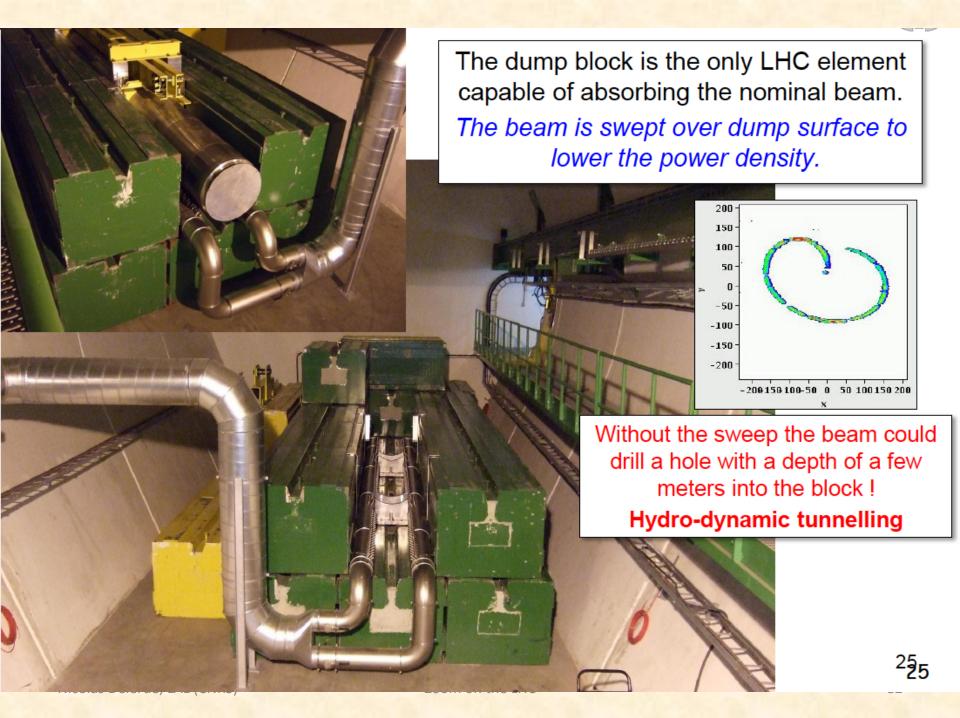

LHC beam dump A complex system, and yet it must be ultra-highly reliable! 15 septum Beam 1 magnets deflect the beam vertically 10 kicker magnets dilute Beam the beam dump block 15 fast 'kicker' ≈ 900 m magnets deflect the beam to the outside Q4R ≈ 500 m Q5R quadrupoles Beam

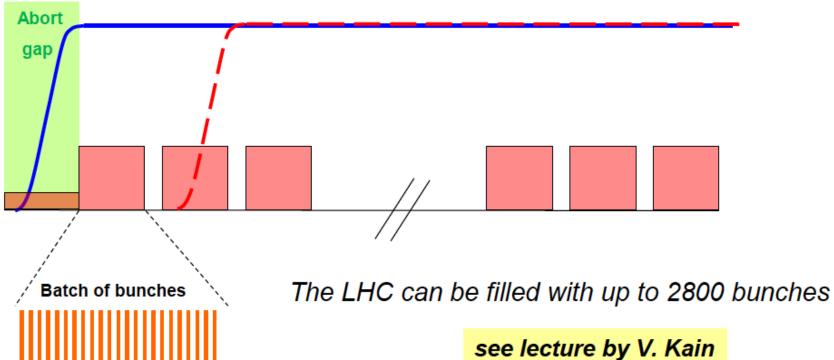

Beam dump synchronisation

- The beam dump must be accurately synchronized to the beam abort gap to avoid spreading beam across the aperture during the kicker rise-time.
- The 3 μs long beam abort gap must be ... free of beam!
- Possible failure modes:
 - The abort gap fills with beams (RF fault, debunching, injection error),
 - The kicker synchronization fails,
 - A kicker fires spontaneously (not synchronized).

Asynchronous dump failure

LHC incident on September 19th 2008

- Last commissioning step of one out of the 8 main dipole electrical circuit in sector 34 : ramp to 9.3kA (5.5 TeV).
- □ At 8.7kA an electrical fault developed in the dipole bus bar located in the interconnection between quadrupole Q24.R3 and the neighboring dipole.

Later correlated to a local resistance of ~220 n Ω – nominal value 0.35 n Ω .

An electrical arc developed which punctured the helium enclosure.

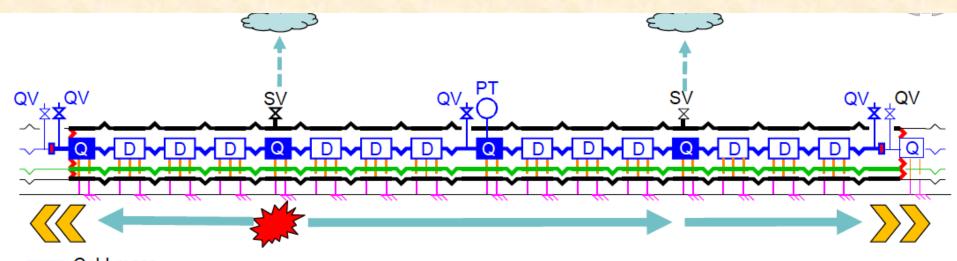

Secondary arcs developed along the arc.

Around 400 MJ from a total of 600 MJ stored in the circuit were dissipated in the cold-mass and in electrical arcs.

Large amounts of Helium were released into the insulating vacuum.

In total 6 tons of He were released.

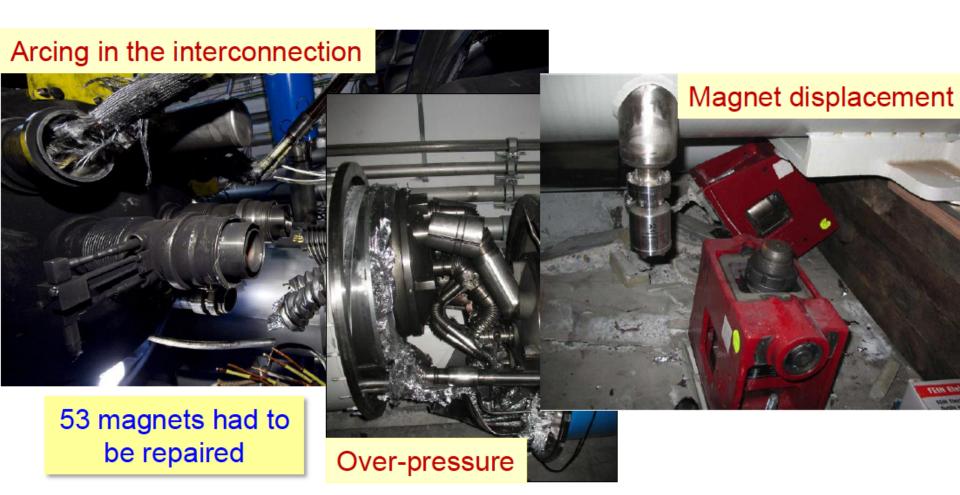

This incident involved magnet powering, but no beam!

- Cold-mass
 Vacuum vessel
 Line E
 Cold support post
 Warm Jack
 Compensator/Bellows
 Vacuum barrier
- Pressure wave propagates along the magnets inside the insulating vacuum enclosure.
- Rapid pressure rise :
 - Self actuating relief valves could not handle the pressure.
 designed for 2 kg He/s, incident ~ 20 kg/s.
 - Large forces exerted on the vacuum barriers (every 2 cells).
 designed for a pressure of 1.5 bar, incident ~ 8 bar.
 - Several quadrupoles displaced by up to ~50 cm.
 - Connections to the cryogenic line damaged in some places.
 - Beam vacuum to atmospheric pressure.

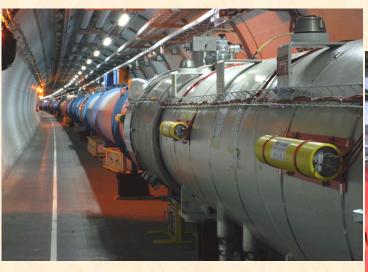

The Helium pressure wave damaged ~600 m of LHC, polluting the beam vacuum over more than 2 km.

Beam Loss Detection

- Role of a Beam Loss Monitor (BLM) system:
 - Protect the machine from damage
 - Dump the beam to avoid magnet quenches (for SC magnets)
 - Diagnostic tool to improve the performance of the accelerator

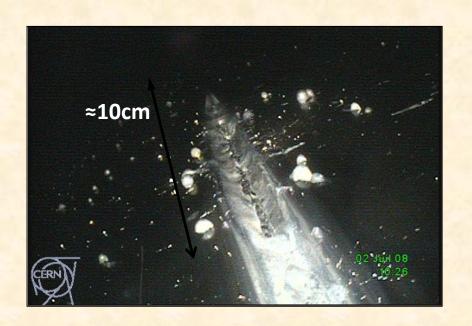

Machine Protection

- Failure in protection
 - loss of complete LHC is possible
- Magnet damage
 - months of downtime & significant cost
- Magnet quench
 - hours of downtime

Stored Energy	
Beam 7 TeV	2 x 362 MJ
2011 Beam 3.5 TeV	above 2 x 100 MJ
Magnets 7 TeV	10 GJ

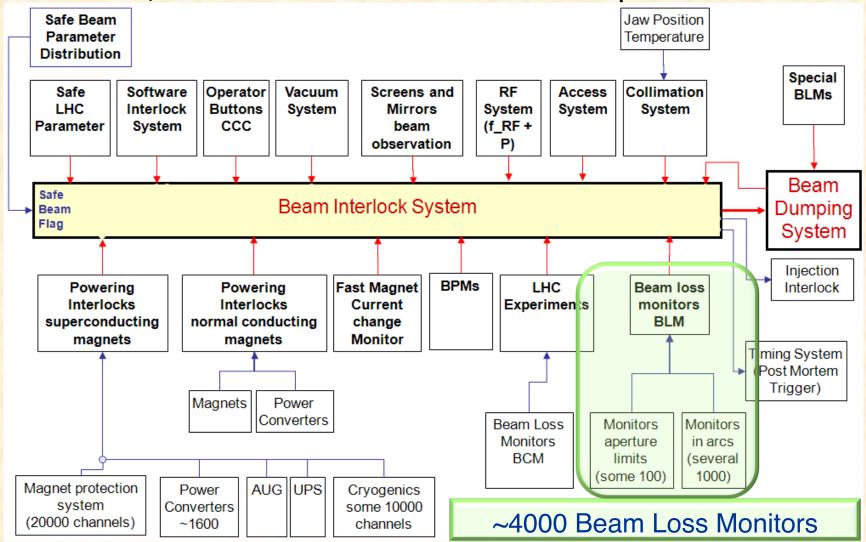

Quench and Damage at 7 TeV	
Quench level	≈ 1mJ/cm³
Damage level	≈ 1 J/cm ³

SPS incident

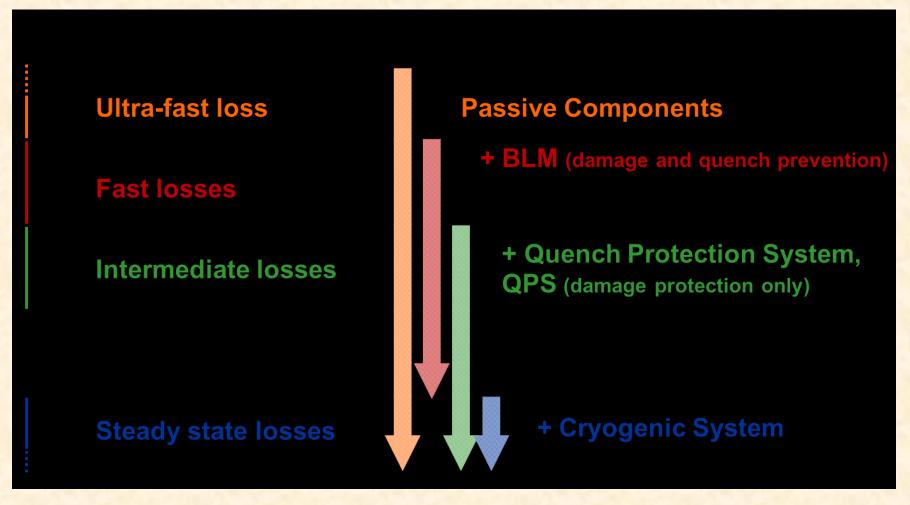

- June 2008
- 2 MJ beam lost at 400GeV

The LHC Machine Protection System

Over 20,000 channels from ~250 user input connections

Beam Loss Durations

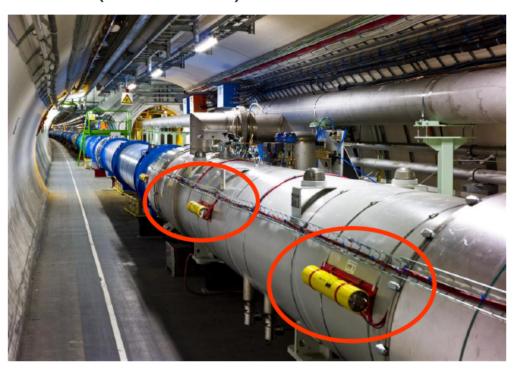

- LHC BLM System
 - Main system to prevent magnet damage from multi-turn beam losses
 - Only system to prevent magnet quench

Beam loss monitoring

- Ionization chambers are used to detect beam losses:
 - Very fast reaction time ~ ½ turn (40 μs)
 - Very large dynamic range (> 10⁶)
- ~3600 chambers (BLMS) are distributed over the LHC to detect beam losses and trigger a beam abort!
- BLMs are good for almost all failures as long as they last ~ a few turns (few 0.1 ms) or more!

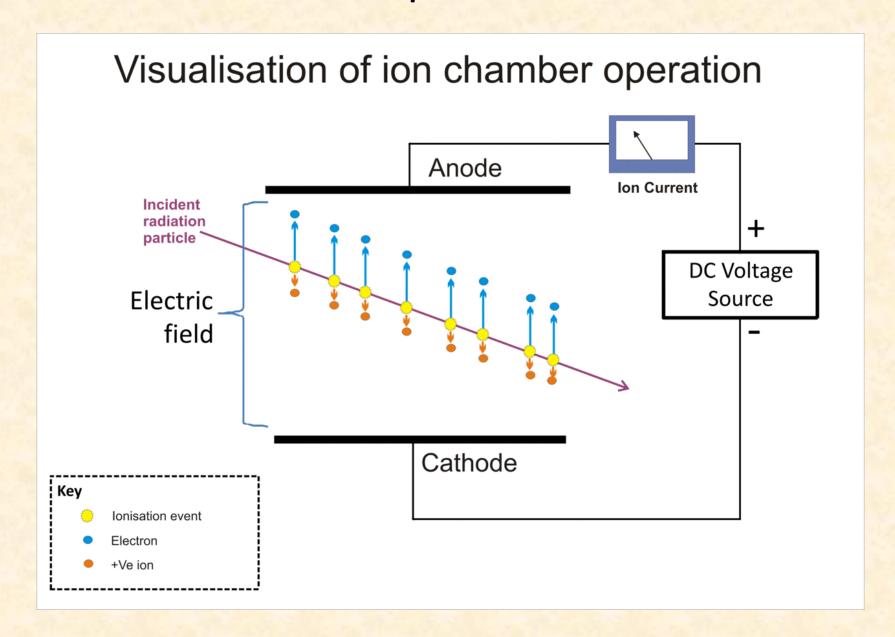

BLM System Challenges

- Design Specifications
 - Reliability
 - tolerable failure rate 10^{-7} per hour per channel $\Rightarrow 10^{-3}$ magnets lost per year (assuming 100 dangerous losses per year)
 - Implies
 - Reliable components, radiation tolerant electronics
 - Redundancy, voting
 - Monitoring of availability and drift of channels
 - Less than 2 false dumps per month (operation efficiency)
 - High dynamic range 10¹³
 - Fast (1 turn, 89 μs) trigger generation for dump signal
 - Quench level determination with uncertainty of factor 2
 - Extensive simulations and measurements
 - Threshold values a function of loss duration and beam energy

Loss Scenarios in the LHC

- Orbit bumps or combination of orbit bump & fast perturbation
 - Much of the LHC controlled automatically with feedbacks
- Leakage from collimation regions
 - Debris reach cold magnets in dispersion suppressors
- Luminosity debris
 - mainly for inner triplets
- Injection losses
- Unidentified Falling Objects (UFOs)
 - anywhere around the ring (more on this later)
- Ion losses
 - Secondary ion beam with different charge / mass ratio
 - Around experiments: Bound-free pair production at the IPs
 - Around collimation regions: nuclear processes in primary collimator
 - Highly localised in dispersion suppressors

Detection Principle for main LHC BLMs

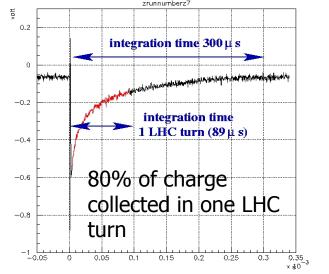

The LHC BLM System

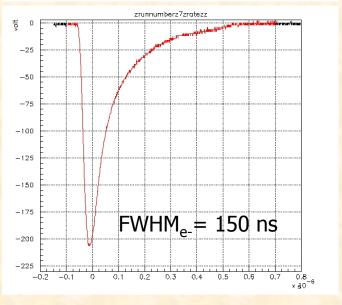

- Ionisation chamber
 - ~3600 installed
 - Gas filled with many metallic electrodes & kV bias
 - Length 50 cm
 - Sensitive volume 1.5 litre N₂ gas filled at 1.1 bar
 - Speed limited by ion collection time
 - Dynamic range of up to 10⁹
 - Limited by leakage current through ceramic & saturation
- Secondary emission monitor
 - ~300 installed
 - Vacuum filled, few electrodes & kV bias
 - Length 10 cm
 - pressure < 10⁻⁷ bar
 - Complements ionisation chamber
 - ~70,000 times smaller gain

Ionisation Chamber Response

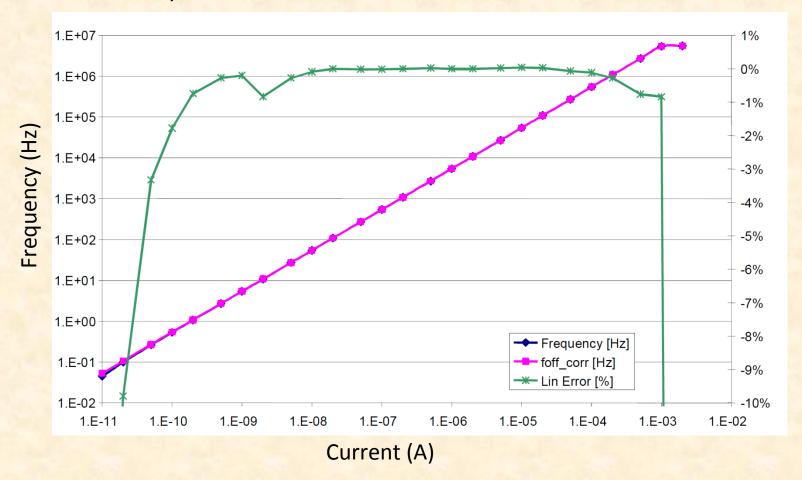

- Sensitivity 54 μC/Gy
- Time response
 - Electron collection 150 ns
 - Ion collection time 80 % at 89 μs
- Absolute calibration +- 30%
- Dynamic (linear range)
 - minimum current < 1 pA
 - maximum current 10 mA
- Radiation tolerance
 - Gain variation:
 - 30 kGy $\Delta \sigma / \sigma < 0.01$
 - 100 MGy $\Delta \sigma / \sigma < 0.05$
 - OK for 30 years of operation

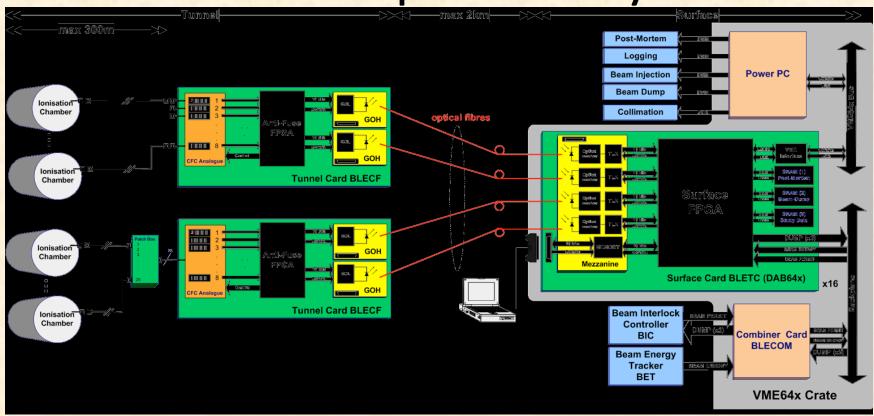

BLM System Electronics

- Linearity
 - Measures currents from tens of pA to 1mA
 - Corresponding frequency from few tenths of a Hz to a few MHz
 - Linearity better than 5%

Linearity error (%)

The BLM Acquisition System

Tunnel electronics (Radiation Hard)

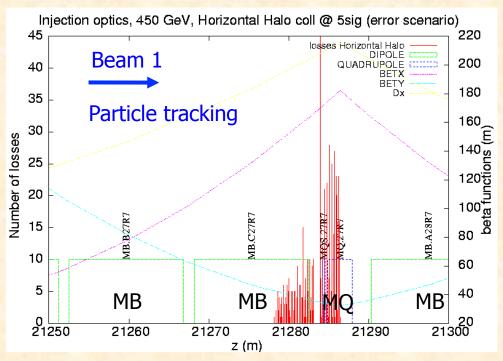

- Current to Frequency Converters (CFCs)
- Analogue to Digital Converters (ADCs)
- Gigabit Optical Links

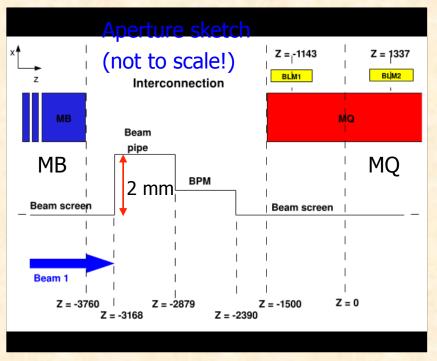

Surface electronics

- Gigabit Optical Receiver
- FPGA for data processing
- SRAM memory for temporary storage
- Non volatile RAM for system settings

Determining Thresholds via Simulations

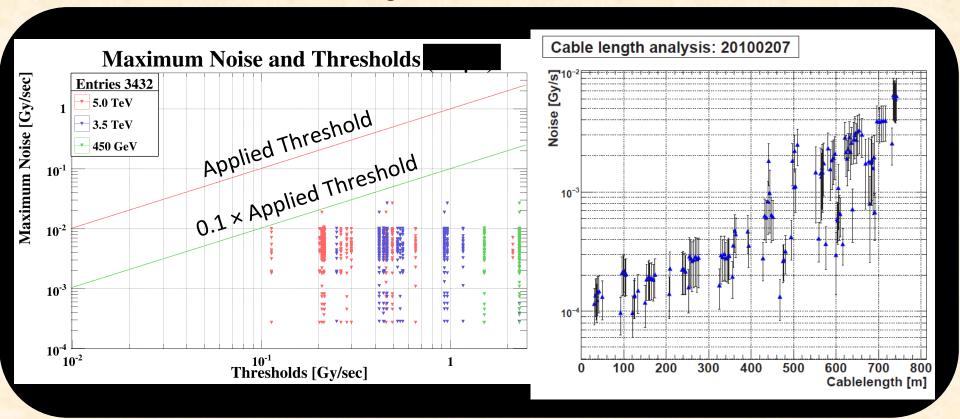

- Particle tracking to determine most likely loss locations
 - Any aperture reduction concentrates location of particle impacts
 - Localises losses at high beta values & reduced aperture
 - Quadrupoles, where orbit deviation and beam size is largest

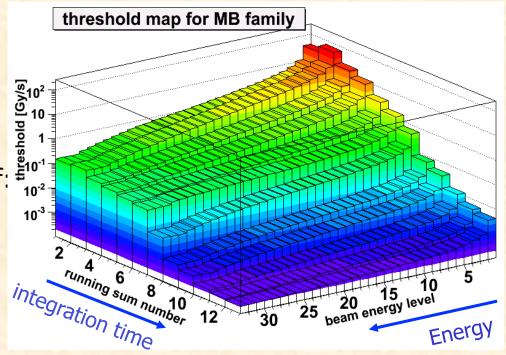

Thresholds Compared to Noise Levels Are the thresholds safely above the noise levels?

- - YES up to 5TeV but noise proportional to cable length
 - Better cable installed in LS1 to allow operation up to 7TeV
 - RadHard ASIC being developed for HL-LHC
 - Would allow mounting front-end electronics near BLM

Threshold Management

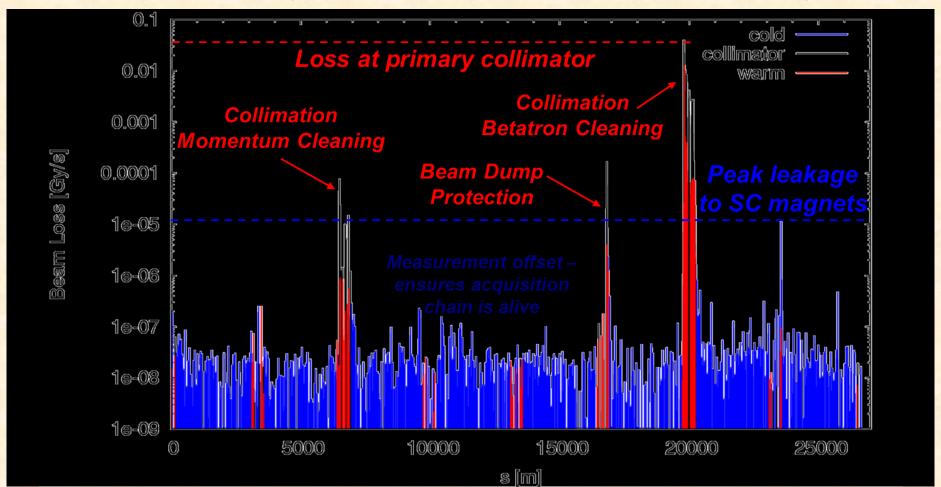

- Beam abort thresholds
 - 12 integration intervals
 - from 40μs to 84s
 - 32 energy levels
 - Managed by family
- Each monitor will abort beam if:
 - One of the 12 integration intervals is over threshold
 - Internal test fails

BLM Functionality - Collimator Verification

- BLM system used both for setting-up and qualifying
- Beam cleaning efficiencies ≥ 99.98% ~ as designed

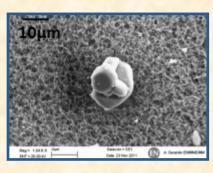

Observing Fast Losses Dealing with Unidentified Falling Objects (UFOs)

- In 2012:
 - 20 beam dumps due to (Un)identified Falling Objects
 - 14 dumps at 4TeV, 3 during ramp, 3 at 450GeV
 - ~17,000 candidate UFOs below BLM thresholds
- At 6.5 7 TeV

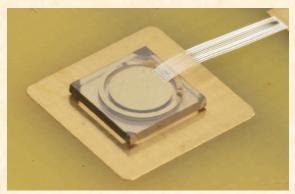

- Quench thresholds much lower hence many more dumps expected

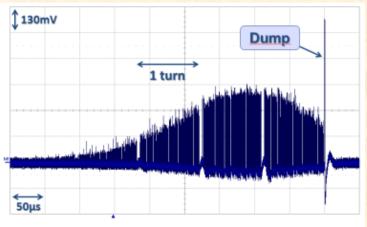

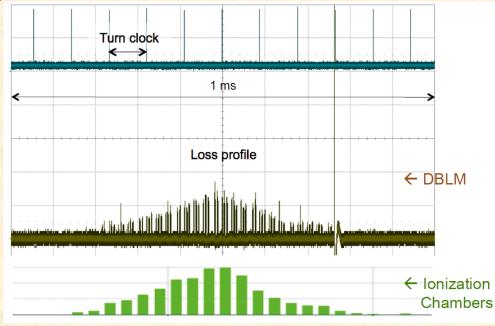

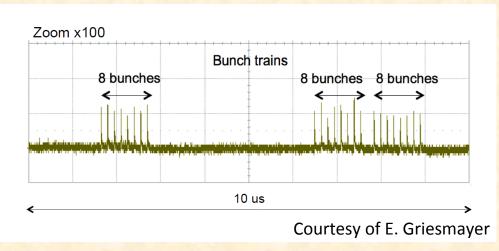

Observing Fast Losses

- Diamond Detectors
 - Fast & sensitive
 - Used in LHC to distinguish bunch by bunch losses

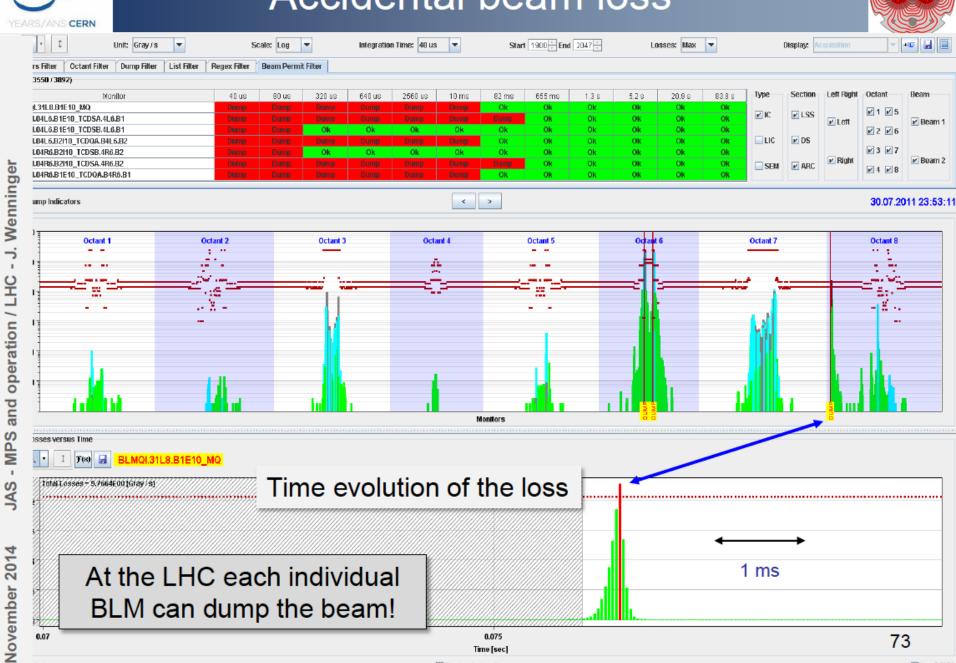

Accidental beam loss

Display Optics Elements

Use DCUM

Surprise, surprise!

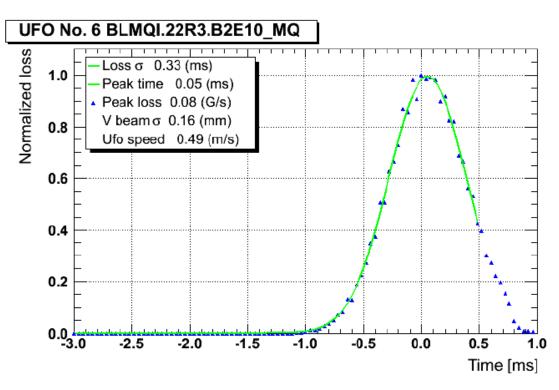

- Very fast beam loss events (~ ms) mainly in supercondcting regions have been THE SURPRISE of LHC operation – nicknamed UFOs*.
 - ~20 dumps by such UFO-type events every year (2010-2012).

The signals are consistent with small (10's μm diameter) dust particles

'entering' the beam.

Time evolution of a UFO-type loss

^{*:}Unidentified Falling Object, acronym borrowed from nuclear fusion community

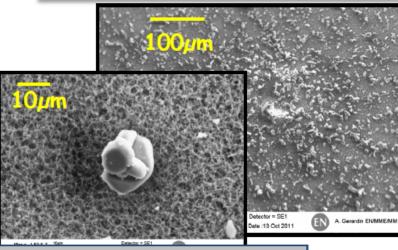

YEARS/ANS CERN

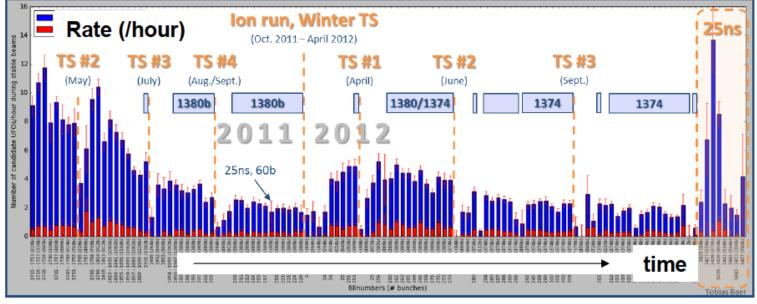

UFO monitoring

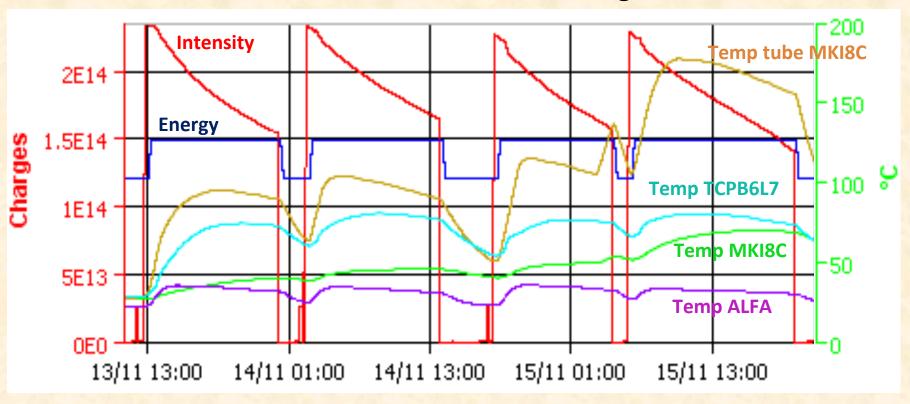

- Monitoring of UFO-like loss events was initiated. The vast majority of events lead to losses below dump threshold.
- □ For LHC injection kickers UFOs could be traced to Al oxide dust → cleaning campaign during the long shutdown.
- There is <u>conditioning</u> with beam:
 - The (non-dumping) UFO-rate drops from ~10/hour to ~2/hour over a year.

In the injection kickers UFOs were traced to Al oxide particles.

Beam induced RF heating?

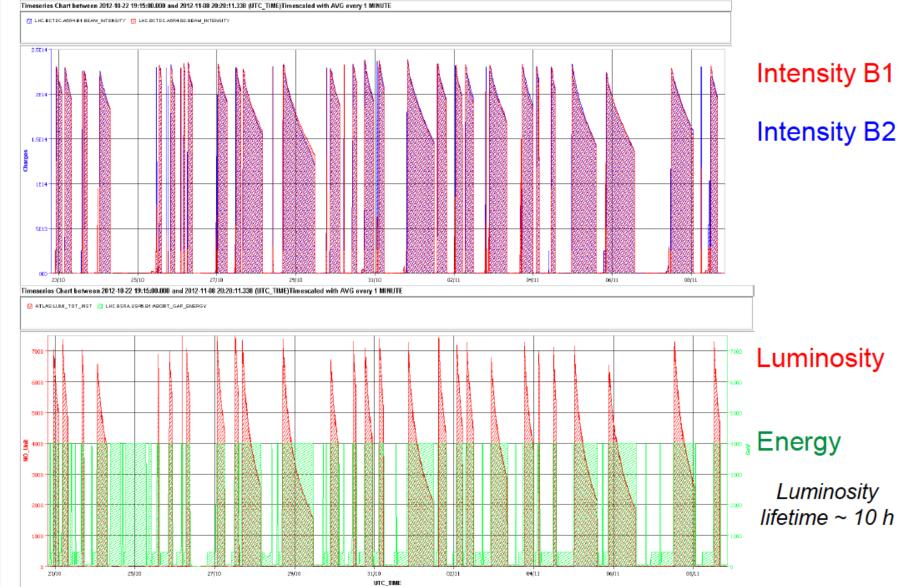

- → Example of temperature increase for kicker, collimator, detector during 4 LHC fills in mid Nov 2012
- → Temperature increase believed to be due to the interaction of beam induced wake fields with the surrounding → also referred to as "RF heating"
- → Temperature increase in LHC devices can cause several issues (damage, delays, dumps)
- Other sources of heating of beam surrounding: synchrotron light, beam losses, electron cloud (not Nicolas Delerge, LAL (CNRS). Zoom on the LHC addressed during this talk)

18 typical LHC days

Summary

- The LHC is a very complex machine.
- The energy stored in the LHC could destroy it in a single turn.
- Its operation must balance availability for HEP and safety.
- All known effects had been correctly anticipated however some unexpected phenomena were discovered.
- Run 1 has been a success...
- ... and run 2 started yesterday!
